Pelagic Fisheries of the Western Pacific Region — 2012 Annual Report

I. Introduction

A. Background to the Annual Report

The Fishery Management Plan (FMP) for Pelagic Fisheries of the Western Pacific Region was implemented by the National Oceanic and Atmospheric Administration's National Marine Fisheries Service (NMFS) on 23 March 1987. The Western Pacific Regional Fishery Management Council (WPRFMC, or Council) developed the FMP to manage the pelagic resources that are covered by the Magnuson Fishery Conservation and Management Act of 1976 and that occur in the US Exclusive Economic Zone (EEZ) around American Samoa, Guam, Hawaii, the Commonwealth of the Northern Mariana Islands (CNMI), and the US possessions in the Western Pacific Region (Johnston Atoll, Kingman Reef and Palmyra, Jarvis, Howland, Baker, Midway, and Wake Islands). In 2010, the Council and NMFS implemented the Pelagics Fishery Ecosystem Plan (FEP) that manages the fisheries while taking ecosystem considerations into account.

Figure 1. **Map of the Western Pacific Region**

The abridged objectives of the Pelagics FEP are to:

- Utilize a science-based ecosystem approach to resource management in an ecologically and culturally-sensitive manner to maintain diverse, productive marine ecosystems.

- Flexible and adaptive management systems that respond quickly to new scientific information and changes in environmental conditions or human use patterns.
- Reduce unsustainable human impacts and foster stewardship through improving public and government awareness and understanding of marine environments.
- Encourage and provide for sustained and substantive participation of local communities in exploration, development, conservation, and management of marine resources.
- Minimize fishery bycatch and waste to the extent practicable.
- Manage and co-manage protected species, protected habitats, and protected areas.
- Promote safety of human life at sea.
- Encourage and support appropriate compliance and enforcement with local and federal fishery regulations.
- Increase collaboration with domestic and foreign regional fishery management organizations, communities, and public to successfully manage marine ecosystems.
- Improve quantity and quality of available information to support marine ecosystem management.

Non-tuna PMUS are sometimes referred to as "other PMUS" in this report. This term is equivalent to PMUS (Pelagic Management Unit Species) used in annual reports previous to 1992, before tunas were included in the management unit.

The PMUS are caught in the troll, longline, handline and pole-and-line (baitboat) fisheries. They are caught in oceanic as well as insular pelagic waters. Most of these species are considered to be epipelagic because they occupy the uppermost layers of the pelagic zone. All are trophically high-level predators. Pelagic fisheries for PMUS are among the most important, if not the dominant, Pacific Island fisheries.

This report contains fishery performance data from each of the four island groups through 2012, and interpretations of trends or important events occurring in the fisheries and recommendations. The Hawaii report is an integration of State of Hawaii Division of Aquatic Resources and NMFS summaries. This report was prepared using reports submitted by the following agencies:

- Territory of American Samoa, Department of Marine and Wildlife Resources
- Territory of Guam, Division of Aquatic and Wildlife Resources
- Territory of Guam, Department of Commerce
- State of Hawaii, Division of Aquatic Resources
- Commonwealth of the Northern Mariana Islands, Division of Fish and Wildlife
- NMFS, Pacific Islands Region (including Pacific Islands Fisheries Science Center, Pacific Islands Regional Office, and Office for Law Enforcement)
- US Coast Guard, District 14
- Pelagic Fisheries Research Program, University of Hawaii

A list of the Pelagic Plan Team members during 2012 and persons responsible for compilation of this report are included in Appendix 1.

B. The Pelagic Species of the Western Pacific Region

The Management Unit Species (MUS) managed under the Pelagic FEP excludes dogtooth tuna (*Gymnosarda unicolor*) and all sharks except the following nine species: pelagic thresher shark (*Alopias pelagicus*), bigeye thresher shark (*Alopias superciliosus*), common thresher shark (*Alopias vulpinus*), silky shark (*Carcharhinus falciformis*), oceanic whitetip shark, (*Carcharhinus longimanus*), blue shark (*Prionace glauca*), shortfin mako shark (*Isurus oxyrinchus*), longfin mako shark (*Isurus paucus*), and salmon shark (*Lamna ditropis*) (Table 1).

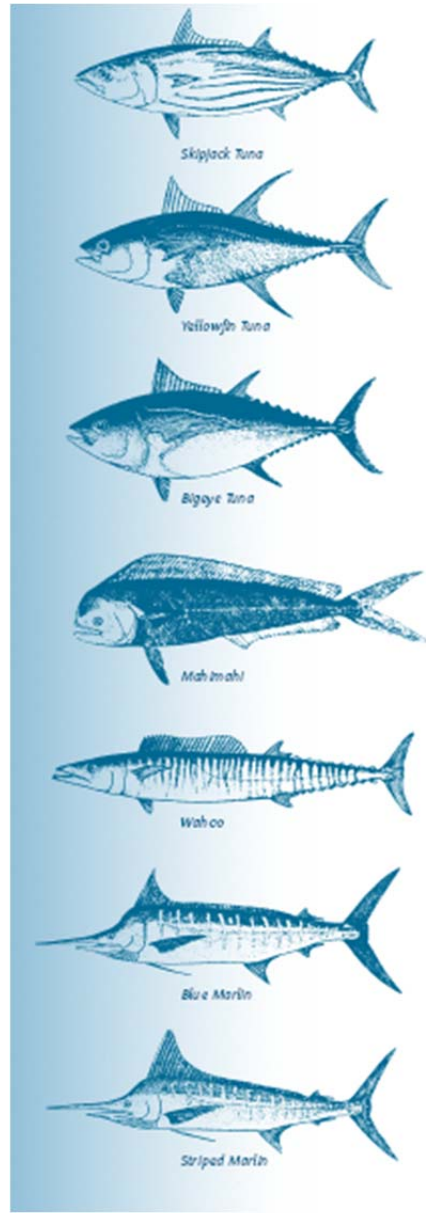

Table 1. Names of Pacific Pelagic Management Unit Species

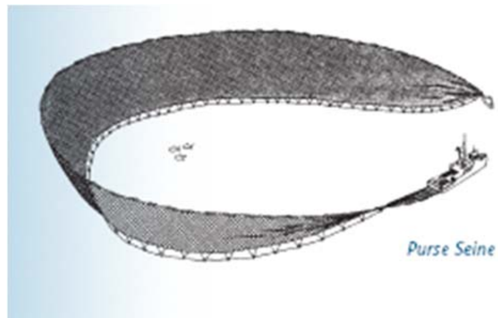
English Common Name	Scientific Name	Samoan or AS local	Hawaiian or HI local	Chamorroan or Guam local	S. Carolinian or NMI local	N. Carolinian or NMI local
Mahimahi (dolphinfishes)	*Coryphaena* spp.	Masimasi	Mahimahi	Botague	Sopor	Habwur
Wahoo	*Acanthocybium solandri*	Paala	Ono	Toson	Ngaal	Ngaal
Indo-Pacific blue marlin Black marlin	*Makaira mazara:* *M. indica*	Sa'ula	A'u, Kajiki	Batto'	Taghalaar	Taghalaar
Striped marlin	*Tetrapturus audax*		Nairagi			
Shortbill spearfish	*T. angustirostris*	Sa'ula	Hebi	Spearfish		
Swordfish	*Xiphias gladius*	Sa'ula malie	A'u kū, Broadbill, Shutome	Swordfish	Taghalaar	Taghalaar
Sailfish	*Istiophorus platypterus*	Sa'ula	A'u lepe	Guihan layak	Taghalaar	Taghalaar
Pelagic thresher shark Bigeye thresher shark Common thresher shark Silky shark Oceanic whitetip shark Blue shark Shortfin mako shark Longfin mako shark Salmon shark	*Alopias pelagicus* *Alopias superciliosus* *Alopias vulpinus* *Carcharhinus falciformis* *Carcharhinus longimanus* *Prionace glauca* *Isurus oxyrinchus* *Isurus paucus* *Lamna ditropis*	Malie	Mano	Halu'u	Paaw	Paaw
Albacore	*Thunnus alalunga*	Apakoa	'Ahi palaha, Tombo	Albacore	Angaraap	Hangaraap
Bigeye tuna	*T. obesus*	Asiasi, To'uo	'Ahi po'onui, Mabachi	Bigeye tuna	Toghu, Sangir	Toghu, Sangir
Yellowfin tuna	*T. albacares*	Asiasi, To'uo	'Ahi shibi	'Ahi, Shibi	Yellowfin tuna	Toghu
Northern bluefin tuna	*T. thynnus*		Maguro			
Skipjack tuna	*Katsuwonus pelamis*	Atu, Faolua, Ga'oga	Aku	Bunita	Angaraap	Hangaraap
Kawakawa	*Euthynnus affinis*	Atualo, Kavalau	Kawakawa	Kawakawa	Asilay	Hailuway
Moonfish	*Lampris* spp	Koko	Opah		Ligehrigher	Ligehrigher
Oilfish family	Gempylidae	Palu talatala	Walu, Escolar		Tekiniipek	Tekiniipek
Pomfret	family Bramidae	Manifi moana	Monchong			
Other tuna relatives	*Auxis* spp, *Scomber* spp; *Allothunus* spp	(various)	Ke'o ke'o, saba (various)	(various)	(various)	(various)

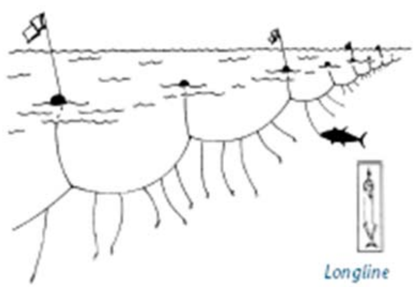
C. Pelagic Gear Types and Fisheries of the Western Pacific Region

U.S. pelagic fisheries in the Western Pacific Region are, with the exception of purse seining, primarily variations of hook-and-line fishing. These include longlining, trolling, handlining, and pole-and-line fishing.



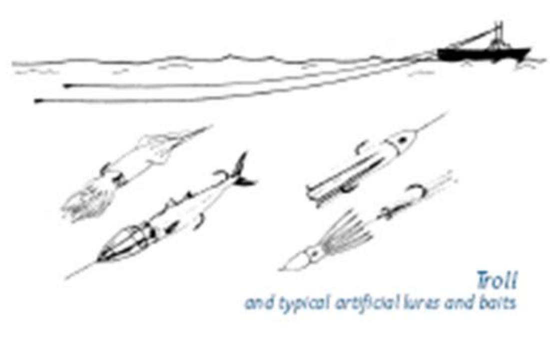
The largest fishery in terms of tonnage of fish landed is the U.S. purse-seine fishery, with catches of skipjack, yellowfin and bigeye tuna amounting to 87,994 mt. However, this fleet has decreased in size from a peak in 1984 of 61 vessels to 14 vessels in 2004, but rebuilt after 2006 to 39 vessels as of 2012.

The U.S. fleet of albacore trollers, based at West Coast ports, amounts to about 400 vessels, fishing primarily in the temperate waters of the North Pacific and landing in 2003 about 17,000 mt of fish. Some vessels from this fleet also fish seasonally for albacore in the South Pacific. In the past catches by this fishery reached about 4,900 mt (in 1991) but more recently catches have amounted to between 200-300 mt. In 2012, 9 trollers fished the South Pacific landing 198 mt of albacore.



U.S. longline vessels in the Western Pacific Region are based primarily in Hawaii and American Samoa, although Hawaii-based vessels targeting swordfish have also fished seasonally out of California. The Hawaii fishery, with 128 vessels, targets a range of species, with vessels setting shallow longlines to catch swordfish or fishing deep to maximize catches of bigeye tuna. Catches by the Hawaii fleet also include yellowfin tuna, mahimahi (dolphinfish, dorado), wahoo, blue and striped marlins, opah (moonfish) and monchong (pomfret). The Hawaii fishery does not freeze its catch, which is sold to the fresh fish and sashimi markets in Hawaii, Japan, and the U.S. mainland.

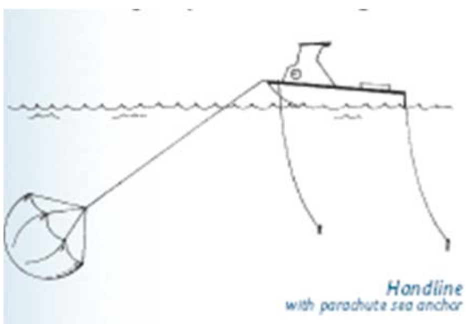
The American Samoa fleet of about 25 active vessels, down from a peak of 70 active vessels in 2001, fishes almost exclusively for albacore tuna, which is landed to two tuna canneries in American Samoa. The combined landings from the tuna and non-tuna pelagic fisheries in 2012 amounted to 9.1 million pounds. In 2012, the combined landings of blue and striped marlins from the longline fishery amounted to 1.5 million pounds, 99% of which were landed in Hawaii.



Trolling and, to lesser extent, handline fishing for pelagics is the largest commercial fishery in terms of participation, although it catches annually a relative modest volume of fish amounting to about 4.6 million lbs in 2012. Part of this catch is made by charter or for-hire fishing vessels. In 2012, there were 1,698 troll vessels and 565 handline vessels in Hawaii, 35 troll vessels in CNMI, 351 troll vessels in

Guam, and 9 troll vessels in American Samoa. Troll and handline catches are dominated by yellowfin tuna in Hawaii, by skipjack tuna in Guam and CNMI, and skipjack and yellowfin tuna in American Samoa. Other commonly caught troll catches include mahimahi, wahoo, and blue marlin. About 93 percent of the troll and handline landings are made by Hawaii vessels.

Troll fishing for pelagics is the commonest recreational fishery in the islands of the Western Pacific Region. The definition of recreational fishing, however, continues to be problematic in a region where many fishermen who are fishing primarily for recreation may sell their fish to cover their expenses. Hawaii's 2012 recreational fishery landings amounted to about 44.4 million lbs, based on surveys of fishermen, with yellowfin tuna landings at about 159,500 lbs (34%). Recreational or non-commercial landings from boats in Guam were about 233,800 lbs in 2012, 40% of which was mahimahi. Recreational or non-commercial landings from boats in CNMI were about 178,400 lbs in 2012, 44% of which was wahoo. Recreational or non-commercial landings from boats in American Samoa were about 8.9 million lbs in 2012, although there is no breakout by species.



In 2012, tuna fisheries in the Western Pacific Ocean as a whole catch about 2.6 million mt of fish, with U.S. fisheries in the Western Pacific Region catching about 10.5% of the total. Most of the catch is taken by fleets of high seas longliners and purse seiners from countries such as Japan, Taiwan, Korea and the nations of Central and South America. More recently, Pacific Island countries such as Papua New Guinea have grown in importance in terms of their large scale purse-seine and longline fisheries. Small scale artisanal longlining is also conducted in Pacific Island countries like Samoa and in South America, where there are thousands of small scale longline vessels fishing in coastal waters.

II. Development and Description of the Fisheries of the Western Pacific Region

A. American Samoa

The islands of American Samoa are an area of modest productivity relative to areas to the north and west. The region is traversed by two main currents: the southern branch of the westward-flowing South Equatorial Current during June - October and the eastward-flowing South Equatorial Counter Current during November - April. Surface temperatures vary between 27°-29° C and are highest in the January - April period. The upper limit of the thermocline in ocean areas is relatively shallow (27° C isotherm at 100m depth) but the thermocline itself is diffuse (lower boundary at 300m depth).

1. Traditional and Historical Pelagic Fisheries

Small-scale longline: This fishery is almost defunct with only one vessel still operating. Most participants in the small-scale domestic longline fishery were indigenous American Samoans with vessels under 50 ft in length, most of which are alia boats under 40 ft in length. The stimulus for American Samoa's commercial fishermen to shift from troll or handline gear to longline gear in the mid-1990s was the fishing success of 28' alia catamarans that engaged in longline fishing in the EEZ around Independent Samoa. Following this example, the fishermen in American Samoa deployed a short monofilament longline, with an average of 350 hooks per set, from a hand-powered reel (WPRFMC, 2000). An estimated 90 percent of the crews working in the American Samoa small-scale alia longline fleet were from Independent Samoa. Like the conventional monohull longline fishery (see below) the predominant catch from the small scale fishery albacore tuna, which is marketed to the local tuna canneries.

***Large-scale longline*:** American Samoa's domestic longline fishery expanded rapidly in 2001. Much of the recent (and anticipated future) growth is due to the entry of monohull vessels larger than 50 ft in length. The number of permitted longline vessels in this sector increased from seven in 2000 to 38 by 2003. Of these, five permits for vessels between 50.1 ft - 70 ft and five permits for vessels larger than 70 ft were believed to be held by indigenous American Samoans as of March 21, 2002. Economic barriers have prevented more substantial indigenous participation in the large-scale sector of the longline fishery. The lack of capital appears to be the primary constraint to substantial indigenous participation in this sector. In 2012, although there are still 38 permitted vessels greater than 50 feet length, only 22 are active compared to the 31 active vessels in 2003.

While the smallest (less than or equal to 40 ft) vessels average 350 hooks per set, a vessel over 50 ft can set 5-6 times more hooks and has a greater fishing range and capacity for storing fish (8-40 mt as compared to 0.5-2 mt on a small-scale vessel). Larger vessels are also outfitted with hydraulically-powered reels to set and haul mainline, and modern electronic equipment for navigation, communications and fish finding. Most are presently being operated to freeze albacore onboard, rather than to land chilled fish. Three vessels that left Hawaii after the swordfish longline fishery closure are operating in the American Samoa tuna longline fishery under new ownership. It does not appear that large numbers of longliners from Hawaii are relocated in American Samoa. Instead, large vessels have participated in the American Samoa longline fishery from diverse ports and fisheries, including the US west coast (6), Gulf of Mexico (3), and foreign countries (4 now under U.S. ownership).

Distant-water purse seine fishery: The US purse seine fleet operating in the central and western Pacific uses large nets to capture skipjack, yellowfin and bigeye tuna near the ocean surface, in free-swimming schools and around fish aggregation devices (FADs) deployed by the fleet. These vessels often land their catches at canneries based in American Samoa. These large vessels (200-250 ft length) could not be economically operated for longline fishing but some former participants in the U.S. purse seine fishery have acquired more suitable vessels and participated in the American Samoa-based longline fishery.

Distant-water jig albacore fishery: Domestic albacore jig vessels also supply tuna to the canneries in American Samoa. Between 1988 and 2001 about 30-55 US vessels participated in the high-seas troll fishery for albacore. This fishery occurs seasonally (December through April) in international waters at 35°-40° S latitude. The vessels range in length from 50 to 120 feet, with the average length about 75 feet. They operate with crews of 3-5 and are capable of freezing 45-90 tons of fish. Currently (2007-2011), only 3-6 vessels have operated in this fishery and catch between 150 and 300 mt of fish annually.

Troll and handline fishery: From October 1985 to the present, catch and effort data in American Samoa fisheries have been collected through a creel survey that includes subsistence and recreational fishing, as well as commercial fishing. However, differentiating commercial troll fishing activity from non-commercial activity can be difficult.

Recreational fishing underwent a renaissance in American Samoa with the establishment of the Pago Pago Game Fishing Association (PPGFA), founded in 2003 by a group of recreational anglers. The motivation to form the PPGFA was the desire to host regular fishing competitions. There are about 15 recreational fishing vessels ranging from 10 ft single engine dinghies to 35 ft twin diesel engine cabin cruisers. The PPGFA has annually hosted international tournaments over the past 15 years, including the Steinlager I'a Lapo'a Game Fishing Tournament (a qualifying event for the International Game Fish Association's Offshore World Championship in Cabo San Lucas, Mexico). The recreational vessels use anchored fish aggregating devices (FADs) extensively, and on tournaments venture to the various outer banks which include the South Bank (35 miles), North East Bank (40 miles NE), South East bank (37 miles SE), 2% bank (40 miles), and East Bank (24 miles East). Several recreational fishermen have aspirations to become charter vessels and are in the process of obtaining captains (6 pack) licenses.

There was no full-time regular charter fishery in American Samoa similar to those in Hawaii or Guam. However, Pago Pago Marine Charters, which is concerned primarily with industrial work such as underwater welding, construction, and salvage, now operates a full-time charter fishery.

Estimation of the volume and value of recreational fishing in American Samoa is not known with any precision. A volume approximation of boat based recreational fishing is generated in the Council's Pelagics Annual Report, based on the annual sampling of catches conducted under the auspices of WPacFIN. Boat-based recreational catches have ranged from 857 to 46,462 lb between 2002 and 2012, with an average of about 14,000 lbs; recreational catch in 2012 was approximately 2,253 lbs.

2. Pelagic Fisheries Development

American Samoan dependence on fishing undoubtedly goes back as far as the peopled history of the islands of the Samoan archipelago, about 3,500 years ago. Many aspects of the culture have changed in contemporary times but American Samoans have retained a traditional social system that continues to strongly influence and depend upon the culture of fishing. Centered around an extended family (`aiga) and allegiance to a hierarchy of chiefs (matai), this system is rooted in the economics and politics of communally-held village land. It has effectively resisted Euro-American colonial influence and has contributed to a contemporary cultural resiliency unique in the Pacific islands region.

The small economy in American Samoa continues to develop. Its two most important sectors are the American Samoa Government (ASG), which receives income and capital subsidies from the federal government, and tuna canning (BOH 1997). In 2011, total export value of commodities was about $17 million; $13.4 million is attributed to canned tuna (ASG DOC Statistical Yearbook, pg. 203, 2011). Private businesses and commerce comprise a smaller third sector.

Unlike some of its South Pacific neighbors, American Samoa has never had a robust tourist industry.

The excellent harbor at Pago Pago, 390,000 square kilometers of EEZ, and certain special provisions of U.S. law form the basis of American Samoa's decades-old fish processing industry (BOH 1997). The territory is exempt from the Nicholson Act, which prohibits foreign ships from landing their catches in U.S. ports. American Samoan products with less than 50 percent market value from foreign sources enter the United States duty free (Headnote 3(a) of the U.S. Tariff Schedule). In 1997 tuna processing directly and indirectly generated about 15 percent of current money wages, 10 to 12 percent of aggregate household income, and 7 percent of government receipts in the territory (BOH 1997) and these numbers are thought to be fairly reliable up until Chicken-of-the-Sea (COS) closed. Prior to the COS tuna cannery closure, canning provided 8,118 jobs (5,538 direct 2,580 indirect) in American Samoa – 45.6 percent of total employment (McPhee and Associates 2008). The COS closure resulted in the loss of approximately 2,000 of those jobs. Cannery exports accounted for the majority of total exports of goods and services (BEA 2011) in 2008-2009, and still do in 2011 (DOC SD 2011). In 2011, 618,000 cases of tuna were exported from American Samoa with a value of approximately $13.4 million (DOC SD 2011).

In 2012, the ASG employed 5,258 people (35 percent of total employment; DOC Statistical Yearbook, pg. 114, 2012), and the private sector employed 7,721 people. Canneries employed only 1,827 people, which is 12% of the people employed. As of 2010, there were 34,767 people 16 years and older in the labor force (statistic is updated every 5 years).

Harsh working conditions, low wages and long fishing trips have discouraged American Samoans from working on foreign longline vessels delivering tuna to the canneries. American Samoans prefer employment on the U.S. purse seine vessels, but the capital-intensive nature of purse seine operations limits the number of job opportunities for locals in that sector as well. However, the presence of the industrial tuna fishing fleet has had a positive economic effect on the local economy as a whole. Ancillary businesses involved in re-provisioning the fishing fleet generate a significant number of jobs and amount of income for local residents.

The tuna processing industry has had a mixed effect on the commercial fishing activities undertaken by American Samoans. The canneries often buy fish from the small-scale domestic longline fleet based in American Samoa, although the quantity of this fish is insignificant compared to cannery deliveries by the U.S. purse seine, U.S. albacore and foreign longline fleets. The ready market provided by the canneries is attractive to the small boat fleet, and virtually all of the albacore caught by the domestic longline fishery is sold to the canneries.

Local fishermen have indicated an interest in participating in the far more lucrative overseas market for fresh fish. To date, however, inadequate shore-side ice and cold storage facilities in American Samoa and infrequent and expensive air transportation links have been restrictive factors.

American Samoa's position in the industry is being eroded by forces at work in the world economy and in the tuna canning industry itself. Whereas wage levels in American Samoa are the US minimum wage, they are considerably higher than in other canned tuna production centers around the world. To remain competitive, U.S. tuna producers are purchasing more raw materials, especially pre-cooked loins, from foreign manufacturers. Tax benefits to US canneries operating in American Samoa have also been tempered by the removal of a provision in the US tax code that previously permitted the tax-free repatriation of corporate income in US territories. Trends in world trade, specifically reductions in tariffs, are reducing the competitive advantage of American Samoa's duty-free access to the US canned tuna market.

3. Administrative or Management Actions to Date

Along with the original measures placed into the Pelagics FMP, the following amendments were made which affected the pelagic fisheries of American Samoa:

FMP AMENDMENT 1 (effective March 1, 1991) defined recruitment overfishing and optimum yield for each PMUS.

FMP AMENDMENT 2 (effective May 26, 1991) implemented permitting and logbook requirements for domestic pelagic longline fishing and transshipment vessel operators.

FMP AMENDMENT 8 (effective Feb. 3, 1999, and July 3, 2003) addressed new requirements under the 1996 Sustainable Fisheries Act, included designations of essential fish habitat, descriptions of fishing communities, overfishing definitions and bycatch.

FMP AMENDMENT 10 (prepared and transmitted to the NMFS for approval in parallel with the
FMP for Coral Reef Ecosystems of the Western Pacific Region) clarified the PMUS by removing all but truly oceanic sharks to the Coral Reef Ecosystems FMP along with dogtooth tuna.

FMP AMENDMENT 11 (effective May 24, 2005) established a limited access system for pelagic longlining in EEZ waters around American Samoa with initial entry criteria based on historical participation in the fishery.

In 2006 NMFS notified the Council that overfishing of Western and Central Pacific yellowfin tuna was occurring and requested the Council to take appropriate action to end the overfishing. The Council was informed that the entire U.S. harvest of yellowfin tuna in the Western and Central Pacific was only about 4 percent of the total area's catch and that NMFS welcomed the Council's participation as a member in international fishery management organizations.

FMP AMENDMENT 14 (partially approved by NMFS on May 16, 2007) was developed in response to NMFS' notifications that Pacific-wide bigeye and Western and Central Pacific yellowfin tuna were subject to overfishing. It contained recommendations regarding both international and domestic management, including a mechanism by which the Council could participate in international negotiations regarding these stocks.

FMP REGULATORY AMENDMENT 7 (effective May 17, 2007) provided pelagic fishery participants the option of using NMFS approved electronic logbooks in lieu of paper logbooks. This measure was implemented to improve the efficiency and accuracy of catch reporting.

FRAMEWORK MEASURE 1 (effective March 1, 2002) established an area seaward of 3 nm out to approximately 50 nm around the islands of American Samoa in which fishing for PMUS is prohibited by vessels greater than 50 feet in length overall that did not land PMUS in American Samoa under a federal longline general permit prior to Nov. 13, 1997.

FMP AMENDMENT 15 (effective December 22, 2008) designated three species of pelagic squid as management unit species, and established permitting, reporting, and observer requirements for squid jig fishing vessels over 50ft (15.4 m) in length.

FEP AMENDMENT 1 (effective September 3, 2010) established eligibility requirements and procedures for reviewing and approving community development plans for Western Pacific fisheries.

FEP AMENDMENT 2 was disapproved on July 11, 2011. The intent was to establish a purse seine area closure in American Samoa.

FEP AMENDMENT 4 (effective June 27, 2011) established a mechanism for specifying annual catch limits for Western Pacific fisheries.

FEP AMENDMENT 5 (effective August 24, 2011) modified gear configurations for the American Samoa longline fishery to reduce sea turtle interactions.

B. Guam

Generally, the major surface current affecting Guam is the North Equatorial Current, which flows westward through the islands. Sea surface temperatures off Guam vary between 80.9° – 84.9° F, depending on the season. The mixed layer extends to depths between 300 and 400 ft.

1. Traditional and Historical Pelagic Fisheries

Guam's pelagic fisheries consist of primarily small, recreational, trolling boats that are either towed to boat launch sites or berthed in marinas and fish only within local waters, either within the EEZ around Guam or on some occasions in the adjacent EEZ waters around the Northern Mariana Islands.

Landings consisted primarily of five major species: mahimahi (*Coryphaena hippurus*), wahoo (*Acanthocybium solandri*), bonita or skipjack tuna (*Katsuwonus pelamis*), yellowfin tuna (*Thunnus albacares*), and Pacific blue marlin (*Makaira mazara*). Other minor pelagic species caught include rainbow runner (*Elagatis bipinnulatus*), great barracuda (*Sphyraena barracuda*), kawakawa (*Euthynnus affinis*), dogtooth tuna (*Gymnosarda unicolor*), double-lined mackerel *(Grammatorcynus bilineatus*), oilfish (*Ruvettus pretiosus*), and three less common species of barracuda.

The number of boats involved in Guam's pelagic or open ocean fishery gradually increased from about 200 vessels in 1982. There were 351 boats active in Guam's domestic pelagic fishery in 2012. A majority of the fishing boats are less than 10 meters (33 feet) in length and are usually owner-operated by fishermen who earn a living outside of fishing. Most fishermen sell a portion of their catch at one time or another and it is difficult to make a distinction between recreational, subsistence, and commercial fishers. A small, but significant, segment of Guam's pelagic fishery is made up of marina-berthed charter boats that are operated primarily by full-time captains and crews.

2. Pelagic Fisheries Development

Fishing in Guam continues to be important not only in terms of contributing to the subsistence needs of the Chamorro people but also in terms of preserving their history and identity. Fishing assists in perpetuating traditional knowledge of marine resources and maritime heritage of the Chamorro culture.

The importance of commercial fishing in Guam lies mainly in the territory's status as a major regional fish transshipment center and re-supply base for domestic and foreign tuna fishing fleets. Among Guam's advantages as a home port are well-developed and highly efficient port facilities in Apra Harbor; an availability of relatively low-cost vessel fuel; a well-established marine supply/repair industry; and recreational amenities for crew shore leave. In addition, the territory is exempt from the Nicholson Act, which prohibits foreign ships from landing their catches in U.S. ports. Initially, the majority of vessels calling in Apra Harbor to discharge frozen tuna for transshipment were Japanese purse seine boats and carrier vessels. In the late 1980s, Guam became an important port for Japanese and Taiwanese longline fleets, but port calls have steadily declined and the transshipment volume has also declined accordingly.

By the early 1990s, an air transshipment operation was also established on Guam. Fresh tuna was flown into Guam from the Federated States of Micronesia and elsewhere on air cargo planes and out of Guam to the Japanese market on wide-body passenger planes. Further, vessels from Japan and Taiwan also landed directly into Guam where their fish was packed and transshipped by air to Japan. A second air transshipment operation began in the mid-1990s; it was transporting to Europe fish that did not meet Japanese sashimi market standards, but this has since ceased operations. Moreover, the entire transshipment industry has contracted markedly with only a few operators still making transshipments to Japan. Annual volumes of tuna transshipped of between 2007 and 2011 averages about 3,400 mt, with a 2012 estimate of 2,222 mt, compared to over 12,000 mt at the peak of operations between 1995 and 2001.

3. Administrative or Management Actions to Date

Along with the original measures placed into the Pelagics FMP, the following amendments were made which affected the pelagic fisheries of Guam:

FMP AMENDMENT 1 (effective March 1, 1991) defined recruitment overfishing and optimum yield for each PMUS.

FMP AMENDMENT 2 (effective May 26, 1991) implemented permitting and logbook requirements for domestic pelagic longline fishing and transshipment vessel operators.

FMP AMENDMENT 5 (effective March 2, 1992) created domestic longline vessel exclusion zones around the Main Hawaiian Islands (MHI) ranging from 50 to 75 nm and a similar 50 nm exclusion zone around Guam and its offshore banks.

FMP AMENDMENT 6 (effective Nov. 27, 1992) specified that all tuna species are designated as fish under U.S. management authority and included tunas and related species as PMUS under the FMP. It also applied the longline exclusion zones of 50 nm around the island of Guam and the 25-75 nm zone around the MHI to foreign vessels.

AMENDMENT 8 (effective Feb. 3, 1999, and July 3, 2003) addressed new requirements under the 1996 Sustainable Fisheries Act, included designations of essential fish habitat, descriptions of fishing communities, overfishing definitions and bycatch.

FMP AMENDMENT 10 (prepared and transmitted to the NMFS for approval in parallel with the FMP for Coral Reef Ecosystems of the Western Pacific Region) clarified the PMUS by removing all but truly oceanic sharks to the Coral Reef Ecosystems FMP along with dogtooth tuna. In 2006 NMFS notified the Council that overfishing of Western and Central Pacific yellowfin tuna was occurring and requested the Council to take appropriate action to end the overfishing. The Council was informed that the entire U.S. harvest of yellowfin tuna in the Western and Central Pacific was only about 4 percent of the total area's catch and that NMFS welcomed the Council's participation as a member in international fishery management organizations.

FMP AMENDMENT 14 (partially approved by NMFS on May 16, 2007) was developed in response to NMFS' notifications that Pacific-wide bigeye and Western and Central Pacific yellowfin tuna were subject to overfishing. It contained recommendations regarding both international and domestic management, including a mechanism by which the Council could participate in international negotiations regarding these stocks.

FMP REGULATORY AMENDMENT 7 (effective May 17, 2007) provided pelagic fishery participants the option of using NMFS approved electronic logbooks in lieu of paper logbooks. This measure was implemented to improve the efficiency and accuracy of catch reporting.

FMP AMENDMENT 15 (effective December 22, 2008) designated three species of pelagic squid as management unit species, and established permitting, reporting, and observer requirements for squid jig fishing vessels over 50ft (15.4 m) in length.

FEP AMENDMENT 1 (effective September 3, 2010) established eligibility requirements and procedures for reviewing and approving community development plans for Western Pacific fisheries.

FEP AMENDMENT 4 (effective June 27, 2011) established a mechanism for specifying annual catch limits for Western Pacific fisheries.

C. Hawaii

The archipelago's position in the Pacific Ocean lies within the clockwise rotating North Pacific Subtropical Gyre, extending from the northern portion of the North Equatorial Current into the region south of the Subtropical High, where the water moves eastward in the North Pacific Current. At the pass between the MHI and the NWHI there is often a westward flow from the region of Kauai along the lee side of the lower NWHI. This flow, the North Hawaiian Ridge Current (NHRC), is extremely variable and can also be absent at times. The analysis of 10 years of shipboard acoustic Doppler current profiler data collected by the NOAA Ship Townsend Cromwell shows mean flow through the ridge between Oahu and Nihoa, and extending to a depth of 200 m.

Imbedded in the mean east-to-west flow are an abundance of mesoscale eddies created from a mixture of wind, current, and sea floor interactions. The eddies, which can rotate either clockwise or counter clockwise, have important biological impacts. For example, eddies create vertical fluxes, with regions of divergence (upwelling) where the thermocline shoals and deep nutrients are pumped into surface waters enhancing phytoplankton production, and also regions of convergence (downwelling) where the thermocline deepens. Sea surface temperatures around the Hawaiian Archipelago experience seasonal variability, but generally vary between 18°-28° C (64°-82° F) with the colder waters occurring more often in the NWHI.

A significant source of inter-annual physical and biological variation around Hawaii are El Niño and La Niña events. During an El Niño, the normal easterly trade winds weaken, resulting in a weakening of the westward equatorial surface current and a deepening of the thermocline in the central and eastern equatorial Pacific. Water in the central and eastern equatorial Pacific becomes warmer and more vertically stratified with a substantial drop in surface chlorophyll.

Physical and biological oceanographic changes have also been observed on decadal time scales. These low frequency changes, termed regime shifts, can impact the entire ocean ecosystem. Recent regime shifts in the North Pacific have occurred in 1976 and 1989, with both physical and biological (including fishery) impacts. In the late 1980's an ecosystem shift from high carrying capacity to low carrying capacity occurred in the NWHI. The shift was associated with the weakening of the Aleutian Low Pressure System (North Pacific) and the Subtropical Counter Current. The ecosystem effects of this shift were observed in lower nutrient and productivity levels and decreased abundance of numerous species in the NWHI including the spiny lobster, the Hawaiian monk seal, various reef fish, the red-footed booby, and the red-tailed tropic bird.

1. Traditional and Historical Pelagic Fisheries

Hawaii’s pelagic fisheries, which include the longline, Main Hawaiian Islands troll and handline, offshore handline, and the aku boat (pole and line) fisheries, are the state’s largest and most valuable fishery sector. The target species are tunas and billfish, but a variety of other species are also important. Collectively, these pelagic fisheries made approximately 32 million lbs of commercial landings with a total ex-vessel value of $106 million in 2012.

The largest component of pelagic catch in 2012 was tunas. Bigeye tuna was the largest component, both in lbs and revenue. Swordfish was the largest component of the billfish catch. Mahimahi was the traditionally largest component of the non-tuna and non-billfish catch, but is now about equal to moonfish (opah) (1,628 lbs and 1,622 lbs respectively).

2. Pelagic Fisheries Development

Fishermen in Hawai'i earned $112.4 million from their commercial harvest in 2012, landing 31 million pounds of finfish and shellfish. The Hawaii longline fishery is by far the most important economically, accounting for about 82 percent of the estimated ex-vessel value of the total commercial fish landings in the state. In 2012, it is estimated that the commercial seafood industry in Hawaii generated sales impacts of $855 million and income impacts of $262 million while supporting approximately 11,000 full and part time jobs jobs in the State of Hawaii. The commercial harvest sector generated 3,800 jobs, $196 million in sales, $71 million in income, and $102 million in value added impacts (NMFS 2012[1]).

Recreational fisheries are also extremely important in the State of Hawaii economically, socially, and culturally. The total estimated pelagic recreational fisheries production in 2011 and 2012 was 10.6 and 12.3 million pounds, respectively. The resident angler population in 2009 was estimated to be 140,000 residents, supplemented by an additional 106,000 visitors who went fishing in Hawaii. These anglers took 2.2 million fishing trips in 2009 (80% were shore-based trips). In 2009, it is estimated that the recreational and charter fisheries in Hawaii generated sales impacts of $460 million, income impacts of $150 million, and value-added impacts of $228 million while supporting approximately 4,300 jobs in the State of Hawaii.

3. Administrative or Management Actions to Date

Along with the original measures placed into the Pelagics FMP, the following amendments were made which affected the pelagic fisheries of Hawaii:

FMP AMENDMENT 1 (effective March 1, 1991) defined recruitment overfishing and optimum yield for each PMUS.

FMP AMENDMENT 2 (effective May 26, 1991) implemented permitting and logbook requirements for domestic pelagic longline fishing and transshipment vessel operators.

FMP AMENDMENT 3 (effective Oct. 14, 1991) created a 50 nm longline exclusion zone around the Northwestern Hawaiian Islands (NWHI) to protect endangered Hawaiian monk seals and also implemented framework provisions for establishing a mandatory observer program to collect information on interactions between longline fishing and sea turtles.

---

1 National Marine Fisheries Service. 2014. Fisheries Economics of the United States, 2012. US Dept. Commerce, NOAA Tech. Memo. NMFS-F/SPO-137, 175p.

FMP AMENDMENT 4 (effective Oct. 10, 1991, through April 22, 1994) established a three-year moratorium on new entry into the Hawaii-based domestic longline fishery and required Hawaii-based longline vessels to carry and use a National Marine Fisheries Service (NMFS)-owned vessel monitoring system (VMS) transmitter to ensure that they do not fish within prohibited areas.

FMP AMENDMENT 5 (effective March 2, 1992) created domestic longline vessel exclusion zones around the Main Hawaiian Islands (MHI) ranging from 50 to 75 nm and a similar 50 nm exclusion zone around Guam and its offshore banks.

FMP AMENDMENT 6 (effective Nov. 27, 1992) specified that all tuna species are designated as fish under U.S. management authority and included tunas and related species as PMUS under the FMP. It also applied the longline exclusion zones of 50 nm around the island of Guam and the 25-75 nm zone around the MHI to foreign vessels.

FMP AMENDMENT 7 (effective June 24, 1994) instituted a limited entry program for the Hawaii-based domestic longline fishery with transferable permits, a limit of 164 vessels, and a maximum vessel size of 101 feet in length overall.

FMP AMENDMENT 8 (effective Feb. 3, 1999, and July 3, 2003) addressed new requirements under the 1996 Sustainable Fisheries Act, included designations of essential fish habitat, descriptions of fishing communities, overfishing definitions and bycatch.

FMP AMENDMENT 9 (under development since early 2000) would manage the harvest and retention of sharks in the Hawaii-based longline fishery.

FMP AMENDMENT 10 (prepared and transmitted to the NMFS for approval in parallel with the FMP for Coral Reef Ecosystems of the Western Pacific Region) clarified the PMUS by removing all but truly oceanic sharks to the Coral Reef Ecosystems FMP along with dogtooth tuna.

In 2006 NMFS notified the Council that overfishing of Western and Central Pacific yellowfin tuna was occurring and requested the Council to take appropriate action to end the overfishing. The Council was informed that the entire U.S. harvest of yellowfin tuna in the Western and Central Pacific was only about 4 percent of the total area's catch and that NMFS welcomed the Council's participation as a member in international fishery management organizations.

FMP AMENDMENT 14 (partially approved by NMFS on May 16, 2007) was developed in response to NMFS' notifications that Pacific-wide bigeye and Western and Central Pacific yellowfin tuna were subject to overfishing. It contained recommendations regarding both international and domestic management, including a mechanism by which the Council could participate in international negotiations regarding these stocks. Amendment 14 also contained measures to implement control dates for Hawaii's non-longline commercial pelagic vessels (70 FR 47781, see above) and purse seine and longline vessels (70 FR 47782, see above), as well as requirements for federal permits and reporting for Hawaii-based non-longline commercial pelagic vessels. NMFS disapproved the Amendment's international measures as premature given ongoing international negotiations as well as the development of a memorandum of understanding by the Councils and the Secretary of Commerce, in consultation with the Secretary of State, regarding participation in U.S. delegations and other issues. NMFS disapproved Amendment 14's domestic permit and reporting requirements as duplicative of existing requirements imposed by the State of Hawaii and stated that they were working with the State to improve their data collection and processing system. NMFS also noted that Amendment 14 met the requirements of the Magnuson-Act regarding overfishing of fisheries that have been determined to be subject to overfishing due to excessive international fishing pressure.

At the request of the Council NMFS issued a control date of March 16, 2007 to notify persons who entered the Hawaii-based pelagic charter fishery after that date that they would not necessarily be assured of continuing participation if a limited entry program was subsequently implemented for their fishery. The control date was issued in response to concerns regarding significant expansion of the charter vessel fleet and its potential to impact billfishes and other pelagic species.

FMP AMENDMENTS 9, 12 and 13 were intended to address issues which have now become moot due to changing circumstances, thus these amendment numbers may be used to designate future amendments.

FMP FRAMEWORK MEASURE 2 (effective June 13, 2002) incorporated the terms and conditions of a Nov. 28, 2000, Biological Opinion issued by the U.S. Fish and Wildlife Service under section 7 of the Endangered Species Act to protect seabirds from longline fishing. These measures require Hawaii-based pelagic longline vessel operators to use blue-dyed bait, strategic offal discards and line shooters with weighted branch lines to mitigate seabird interactions when fishing north of 23° N. Also included was a requirement that all Hawaii-based longline vessel owners and operators annually attend a protected species workshop conducted by NMFS.

FMP REGULATORY AMENDMENT 1 (effective June 9, 2002) incorporated the reasonable and prudent alternative of a March 2001 Biological Opinion issued by NMFS under section 7 of the Endangered Species Act. To mitigate interactions with sea turtles, this amendment prohibits shallow set pelagic longlining north of the equator by vessels managed under the FMP and closed waters between 0° and 15°N from April through May of each year to longline fishing. It also institutes sea turtle handling requirements for all vessels using hooks to target pelagic species in the region's EEZ waters.

FMP REGULATORY AMENDMENT 2 (effective Oct. 4, 2002) established federal permit and reporting requirements for any vessel using troll or handline gear to catch PMUS in EEZ waters around the Pacific Remote Island Areas of Kingman Reef; Howland, Baker, Jarvis, Johnston and Wake Islands; and Palmyra and Midway Atolls.

FMP REGULATORY AMENDMENT 3 (effective April 1, 2005) reopened swordfish longline fishing in Hawaii. The amendment requires vessels targeting swordfish to use mackerel type bait and 18/0 circle hooks. It also set an effort limit of 2,120 set per year and hard caps on loggerhead and leatherback turtles takes, which if reached would close the fishery for the remainder to the year.

FMP REGULATORY AMENDMENT 5 (effective January 18, 2006) allowed operators of Hawaii-based longline vessels fishing north of 23 degrees north latitude, as well as those targeting swordfish south of 23 degrees north, to utilize side-setting to reduce seabird interactions in lieu of the seabird mitigation measures required by Framework Measure 1. Side-setting was tested on Hawaii-based longline vessels and found to be highly effective in reducing seabird interactions.

At the request of the Council NMFS published a temporary rule removing the delay in effectiveness for closing the Hawaii-based longline shallow-set swordfish fishery as a result of it having reached one of its turtle interaction limits (71 FR 14416). This rule was implemented as vessel communications had improved to the point that vessel operators could be immediately notified of a closure, thus removing the possibility of exceeding a turtle limit during the notification period. This rule was effective March 20, 2006 through September 18, 2006.

FMP REGULATORY AMENDMENT 6 (effective March 28, 2007) made the above temporary rule permanent.

FMP REGULATORY AMENDMENT 7 (effective May 17, 2007) provided pelagic fishery participants the option of using NMFS approved electronic logbooks in lieu of paper logbooks. This measure was implemented to improve the efficiency and accuracy of catch reporting.

NMFS published a temporary rule effective March 20, 2006 through December 31, 2006 closing the Hawaii-based longline swordfish fishery for the remainder of the calendar year due to its having reached its annual limit of 17 interactions with loggerhead turtles.

CONTROL DATE of June 19, 2008 set for Hawaii-based pelagic charter fishery. Anyone who enters this fishery after this control date is not guaranteed future participation in the fishery if the Western Pacific Regional Fishery Management Council recommends, and NMFS approves, management measures for this fishery (e.g. limited entry).

FMP AMENDMENT 15 (effective December 22, 2008) designated three species of pelagic squid as management unit species, and established permitting, reporting, and observer requirements for squid jig fishing vessels over 50ft (15.4 m) in length.

FEP AMENDMENT 1 (effective September 3, 2010) established eligibility requirements and procedures for reviewing and approving community development plans for Western Pacific fisheries.

FEP AMENDMENT 4 (effective June 27, 2011) established a mechanism for specifying annual catch limits for Western Pacific fisheries.

D. Commonwealth of the Northern Marianas Islands

Generally, the major surface current affecting CNMI is the North Equatorial Current, which flows westward through the islands, however the Subtropical Counter Current affects the Northern Islands and generally flows in a easterly direction. Depending on the season, sea surface temperatures near the Northern Mariana Islands vary between 80.9° – 84.9° F. The mixed layer extends to between depths of 300-400 ft.

1. Traditional and Historical Pelagic Fisheries

The CNMI's pelagic fisheries occur primarily from the island of Farallon de Medinilla south to the island of Rota. Trolling is the primary fishing method utilized in the pelagic fishery. The pelagic fishing fleet consists primarily of vessels less than 24 ft in length, which usually have a limited 20-mile travel radius from Saipan.

The primary target and most marketable species for the pelagic fleet is skipjack tuna (>60% of 2012 commercial landings). Yellowfin tuna and mahimahi are also easily marketable species but are seasonal. During their runs, these fish are usually found close to shore and provide easy targets for the local fishermen. In addition to the economic advantages of being near shore and their relative ease of capture, these species are widely accepted by all ethnic groups which has kept market demand fairly high.

2. Pelagic Fisheries Development

Fishery resources have played a central role in shaping the social, cultural and economic fabric of the CNMI. The aboriginal peoples indigenous to these islands relied on seafood as their principal source of protein and developed exceptional fishing skills. Later immigrants to the islands from East and Southeast Asia also possessed a strong fishing tradition. Under the MSA, the CNMI is defined as a fishing community.

In the early 1980s, U.S. purse seine vessels established a transshipment operation at Tinian Harbor. The CNMI is exempt from the Jones Act, which requires the use of U.S.-flag and U.S.-built vessels to carry cargo between U.S. ports. The U.S. purse seiners took advantage of this exemption by offloading their catch at Tinian onto foreign vessels for shipment to tuna canneries in American Samoa; however this operation closed in the 1990s. Over the past ten years a small 2-4 vessel longline fishing operation has operated in the CNMI but this ceased in 2012.

3. Administrative or Management Actions to Date

Along with the original measures placed into the Pelagics FMP, the following amendments were made which affected the pelagic fisheries of CNMI:

FMP AMENDMENT 1 (effective March 1, 1991) defined recruitment overfishing and optimum yield for each PMUS.

FMP AMENDMENT 2 (effective May 26, 1991) implemented permitting and logbook requirements for domestic pelagic longline fishing and transshipment vessel operators.

FMP AMENDMENT 8 (effective Feb. 3, 1999, and July 3, 2003) addressed new requirements under the 1996 Sustainable Fisheries Act, included designations of essential fish habitat, descriptions of fishing communities, overfishing definitions and bycatch.

FMP AMENDMENT 10 (prepared and transmitted to the NMFS for approval in parallel with the FMP for Coral Reef Ecosystems of the Western Pacific Region) clarified the PMUS by removing all but truly oceanic sharks to the Coral Reef Ecosystems FMP along with dogtooth tuna.

In 2006 NMFS notified the Council that overfishing of Western and Central Pacific yellowfin tuna was occurring and requested the Council to take appropriate action to end the overfishing. The Council was informed that the entire U.S. harvest of yellowfin tuna in the Western and Central Pacific was only about 4 percent of the total area's catch and that NMFS welcomed the Council's participation as a member in international fishery management organizations.

FMP AMENDMENT 14 (partially approved by NMFS on May 16, 2007) was developed in response to NMFS' notifications that Pacific-wide bigeye and Western and Central Pacific yellowfin tuna were subject to overfishing. It contained recommendations regarding both international and domestic management, including a mechanism by which the Council could participate in international negotiations regarding these stocks.

FMP REGULATORY AMENDMENT 7 (effective May 17, 2007) provided pelagic fishery participants the option of using NMFS approved electronic logbooks in lieu of paper logbooks. This measure was implemented to improve the efficiency and accuracy of catch reporting.

CONTROL DATE of June 19, 2008 was set for the CNMI pelagic longline fishery. Anyone who enters this fishery after this control date is not guaranteed future participation in the fishery if the Western Pacific Regional Fishery Management Council recommends, and NMFS approves, management measures for this fishery (e.g. limited entry).

FMP AMENDMENT 15 (effective December 22, 2008) designated three species of pelagic squid as management unit species, and established permitting, reporting, and observer requirements for squid jig fishing vessels over 50ft (15.4 m) in length.

FEP AMENDMENT 1 (effective September 3, 2010) established eligibility requirements and procedures for reviewing and approving community development plans for Western Pacific fisheries.

FEP AMENDMENT 3 (effective June 27, 2011) established a purse seine area closure and longline area closure in CNMI, of which only the longline closure was approved.

FEP AMENDMENT 4 (effective June 27, 2011) established a mechanism for specifying annual catch limits for Western Pacific fisheries.

E. Pacific Remote Island Areas

Baker Island lies within the westward flowing South Equatorial Current. Baker Island also experiences an eastward flowing Equatorial Undercurrent that causes upwelling of nutrient and plankton rich waters on the west side of the island (Brainard et. al 2005). Sea surface temperatures of pelagic EEZ waters around Baker Island are often near 30° C. Although the depth of the mixed layer in the pelagic waters around Baker Island is seasonally variable, average mixed layer depth is around 100 m.

Howland Island lies within the margins of the eastward flowing North Equatorial Counter Current and the margins of the westward flowing South Equatorial Current. Sea surface temperatures of pelagic EEZ waters around Baker Island are often near 30° C. Although the depth of the mixed layer in the pelagic waters around Howland Island is seasonally variable, average mixed layer depth is around 70 m – 90 m.

Jarvis Island lies within the South Equatorial Current which runs in a westerly direction. Sea surface temperatures of pelagic EEZ waters around Jarvis Island are often 28°- 30° C. Although depth of the mixed layer in the pelagic waters around Jarvis Island is seasonally variable, average mixed layer depth is around 80 m.

Palmyra Atoll and Kingman Reef lie in the North Equatorial Counter-current, which flow in a west to east direction. Sea surface temperatures of pelagic EEZ waters around Palmyra Atoll are often 27°- 30° C. Although the depth of the mixed layer in the pelagic waters around Kingman Reef is seasonally variable, average mixed layer depth is around 80 m.

Sea surface temperatures of pelagic EEZ waters around Johnston Atoll are often 27°- 30° C. Although the depth of the mixed layer in the pelagic waters around Johnston Atoll is seasonally variable, average mixed layer depth is around 80 m.

Sea surface temperatures of pelagic EEZ waters around Wake Island are often 27°- 30° C. Although the depth of the mixed layer in the pelagic waters around Wake Atoll is seasonally variable, average mixed layer depth is around 80 m.

1. Traditional and Historical Pelagic Fisheries

As many tropical pelagic species (e.g. skipjack tuna) are highly migratory, the fishing fleets targeting them often travel great distances. Although the EEZ waters around Johnston Atoll and Palmyra Atoll are over 750 nm and 1000 nm (respectively) away from Honolulu, the Hawaii longline fleet does seasonally fish in those areas. For example, the EEZ around Palmyra is visited by Hawaii-based longline vessels targeting yellowfin tuna, whereas at Johnston Atoll, albacore tuna is often caught in greater numbers than yellowfin or bigyeye tuna. Similarly, the U.S. purse seine fleet also targets pelagic species (primarily skipjack tuna) in the EEZs around some PRIA, specifically, the equatorial areas of Howland, Baker, and Jarvis Islands. The combined amount of fish harvested from these areas from the U.S. purse seine on average is less than 5 percent of their total annual harvest.

2. Pelagic Fisheries Development

The USFWS prohibits fishing within the Howland Island, Jarvis Island, and Baker Island National Wildlife Refuge (NWR) boundaries. Currently, Howland Island and Baker Island are uninhabited. The USFWS manages Johnston Atoll as a National Wildlife Refuge, but does allow some recreational fishing within the Refuge boundary.

3. Administrative or Management Actions to Date

Along with the original measures placed into the Pelagics FMP, the following amendments were made which affected the pelagic fisheries of the PRIAs:

FMP AMENDMENT 1 (effective March 1, 1991) defined recruitment overfishing and optimum yield for each PMUS.

FMP AMENDMENT 2 (effective May 26, 1991) implemented permitting and logbook requirements for domestic pelagic longline fishing and transshipment vessel operators.

FMP AMENDMENT 8 (effective Feb. 3, 1999, and July 3, 2003) addressed new requirements under the 1996 Sustainable Fisheries Act, included designations of essential fish habitat, descriptions of fishing communities, overfishing definitions and bycatch.

FMP AMENDMENT 10 (prepared and transmitted to the NMFS for approval in parallel with the FMP for Coral Reef Ecosystems of the Western Pacific Region) clarified the PMUS by removing all but truly oceanic sharks to the Coral Reef Ecosystems FMP along with dogtooth tuna.

In 2006 NMFS notified the Council that overfishing of Western and Central Pacific yellowfin tuna was occurring and requested the Council to take appropriate action to end the overfishing. The Council was informed that the entire U.S. harvest of yellowfin tuna in the Western and Central Pacific was only about 4 percent of the total area's catch and that NMFS welcomed the Council's participation as a member in international fishery management organizations.

FMP AMENDMENT 14 (partially approved by NMFS on May 16, 2007) was developed in response to NMFS' notifications that Pacific-wide bigeye and Western and Central Pacific yellowfin tuna were subject to overfishing. It contained recommendations regarding both international and domestic management, including a mechanism by which the Council could participate in international negotiations regarding these stocks.

FMP REGULATORY AMENDMENT 7 (effective May 17, 2007) provided pelagic fishery participants the option of using NMFS approved electronic logbooks in lieu of paper logbooks. This measure was implemented to improve the efficiency and accuracy of catch reporting.

FMP REGULATORY AMENDMENT 2 (effective Oct. 4, 2002) established federal permit and reporting requirements for any vessel using troll or handline gear to catch PMUS in EEZ waters around the Pacific Remote Island Areas of Kingman Reef; Howland, Baker, Jarvis, Johnston and Wake Islands; and Palmyra and Midway Atolls.

FMP AMENDMENT 15 (effective December 22, 2008) designated three species of pelagic squid as management unit species, and established permitting, reporting, and observer requirements for squid jig fishing vessels over 50ft (15.4 m) in length.

FEP AMENDMENT 1 (effective September 3, 2010) established eligibility requirements and procedures for reviewing and approving community development plans for Western Pacific fisheries.

FEP AMENDMENT 4 (effective June 27, 2011) established a mechanism for specifying annual catch limits for Western Pacific fisheries.

III. The Current Status of Pelagic Fisheries of the Western Pacific Region

A summary of the total pelagic landings during 2011 in the Western Pacific and the percentage change between 2011 and 2012 is shown in Table 2.

Table 2. Total pelagic landings in lbs in the Western Pacific Region in 2012

	American Samoa		Guam		CNMI		Hawaii	
Species	**Lbs**	**% change**	**Lbs**	**% change**	**Lbs**	**% change**	**Lbs**	**% change**
Swordfish	31,179	11.37%					3,094,000	-13.31%
Blue marlin	80,471	-7.06%	12,718	-32.69%	9,751	86.44%	951,000	-23.74%
Striped marlin	16,306	163.34%					648,000	-22.40%
Other billfish	10,800	27.81%	3614				416,000	-29.61%
Mahimahi (dolphinfish)	22,802	4.26%	84,504	-7.02%	39,235	-28.58%	2,007,000	23.28%
Wahoo	187851	-32.51%	44,642	19.51%	18,456	60.26%	809,000	19.85%
Opah (moonfish)	7,507	28.81%					1,593,000	-1.79%
Pomfrets (monchong)	977	-5.88%	113	100.00%			710,000	68.25%
Sharks (whole wt)	7,150	5.77%		-100.00%			181,000	-4.74%
Albacore tuna	7,054,206	42.93%					2,009,000	15.86%
Bigeye tuna	383,023	9.77%					14,022,000	3.90%
Bluefin tuna							1000	100.00%
Skipjack tuna	637,461	167.19%	313,277	-10.54%	288,642	30.27%	907,000	-17.92%
Yellowfin tuna	824,424	-18.70%	29,609	-63.81%	73,707	79.75%	4,098,000	5.70%
Other pelagics	385	-83.58%	6,707	-9.09%	2,756	-70.16%	656,000	786.49%
Total	9,264,542	36.67%	495,184	-15.61%	457,227	32.47%	32,102,000	3.34%

N**ote: Total Pelagic Landings are based on commercial reports and/or creel surveys. "Other pelagics" may include Dogtooth Tuna, Rainbow Runner, Barracudas, Kawakawa, Pomfrets, Oilfish, and Misc Pelagic Fish categories**

IV. 2012 International and Region-wide Pelagics Plan Team Recommendations

There were no recommendations made by the Pelagics Plan Team in 2012, other than content edits to this report.

V. Data Modules

A. American Samoa

Introduction
The pelagic fishery in American Samoa is, and has been, an important component of the American Samoan domestic economy. Prior to 1995, the pelagic fishery was largely a troll fishery. Horizontal longlining was introduced to the Territory by Western Samoan fishermen in 1995. Local fishers have found longlining worthwhile because they land more pounds with less effort and use less gasoline for trips. Initially the vessels used in longlining were “alias,” which are locally built, twin-hulled (wood with fiberglass or aluminum) vessels about 30 feet long, powered by 40HP gasoline outboard engines. Larger monohull vessels capable of longer multi-day trips began joining the longline fleet soon after the alias. Monohull vessels now dominate the fleet and landings. There are presently only a few alias participating in the fishery. Commercial troll vessels have also declined. Federal longline logbooks were implemented during 1996. Two 50-mile area closures for vessels longer than 50 feet were implemented by WPRFMC and NMFS during 2002; one surrounding Swains Island and one surrounding Tutuila and Aunu’u Islands. Federal longline limited entry permits were issued during December of 2005. Albacore is the primary species caught longlining; the bulk of the longline catch is sold to the Pago Pago canneries. Some of the catch is sold to stores, restaurants and local residents, and some is donated for family functions.

Pago Pago Harbor on the island of Tutuila is a regional base for the trans-shipment and processing of tuna taken by domestic fleets from other South Pacific nations, the distant-waters longline fleets, and purse seine fleets. Purse seine vessels land skipjack, yellowfin and other tunas, with little albacore. Purse seine and non-US vessel landings are not included in this report.

Fishery Data History
Prior to 1985, only commercial landings were monitored. From October 1985 to the present, data was collected through a boat-based creel survey including subsistence, recreational, and commercial fishing sectors. In September 1990, a Commercial Purchase (receipt book) System was instituted requiring all businesses in Samoa that buy fish commercially, except for the canneries, to submit a copy of their purchase receipts to Department of Marine and Wildlife Resources (DMWR). In January 1996, in response to the developing longline fishery, a federal longline logbook system was implemented. All longline fishermen are required to obtain a federal permit and submit logs containing detailed data on each set including catch composition. From 1996 through 1999, logbooks submitted by local longliners were edited in American Samoa and sent to the NMFS Honolulu Lab weekly for further editing and data processing. Beginning in 2000, logbook data has been electronically entered and maintained in American Samoa and periodically uploaded to NMFS servers in Hawaii.

Changes to the algorithms for expanding the boat-based creel survey data were described in the 2008 Pelagics Annual Report. These changes were necessary due to peculiarities in the historical data and the emergence of multi-day trips. Data from 1982-1985 were left unchanged; data from 1986-2006 were re-expanded. This recalculation accounts for differences in figures and tables between annual reports issued prior 2008 and subsequent reports. Additionally, in 2000, larger fish began to be measured rather than weighed, and the creel survey system was modified to calculate and incorporate length to weight conversions. Issuance of cannery sampling forms began in 2001. Cannery sampling forms allow fishery managers to determine, for each species, whether catch was sold to small local vendors, to the canneries, or was unsold. Lastly, the method for determining price per pound was revised in 2001.

2012 Summary - American Samoa Pelagic Fishery

Total landings: This category refers to all fish returned to shore for commercial, recreational, or subsistence use.

Commercial landings: This category refers to that portion of the total landings that was sold commercially in American Samoa to canneries and other local businesses. Subsistence and recreational landing are excluded.

Landings (pounds): The estimated annual pelagic landings have varied widely, ranging from 1 to 15 million pounds between 1998 and 2011. Approximately 8.9 million pounds of pelagic species are estimated to have been landed in American Samoa in 2012, an increase of about 27% from 2011. Landings consisted mainly of wahoo and four major tuna species – albacore, yellowfin, bigeye, and skipjack. Other species that made up most of the total landings are blue marlin, swordfish and mahimahi. Tuna species made up 96% of the total landings; albacore tuna comprised 80% of the tuna landings, while yellowfin contributed 9% and skipjack comprised 6%. Non-tunas and other pelagic species made up 4% of the landings.

Effort: The number of longline boats landing any pelagic species gradually decreased from 62 in 2001 to 22 in 2012. These 22 boats deployed 4,068 sets with over 11.7 million hooks. The longline boats landing pelagic species decreased by two in 2012, continuing the declining trend over the past ten years. Two longline alias in the longline fishery are very active. One participates 100% in the longline fishery and the other sometimes participates in the bottomfish fishery. Hardly any interviews were collected from these longline alias because their returning time was always at midnight or early morning before the creel survey begins.

Longline CPUE: The longline CPUE for albacore varied from 18 to 12 fish per 1000 hooks between 2006 and 2011. The 2012 catch rate for albacore increased by 23% from 2011. In 2012, the skipjack CPUE increased by 72%, while yellowfin CPUE decreased by 40%. Bigeye tuna CPUE remained constant at 0.7. CPUE for all tunas increased by 22% in 2012 (Table 5C).

Pounds-Per-Hour Trolling: Average pelagic catch pounds-per-hour trolling increased 0.8% from 2011. This is the highest rate in the fishery history at 52 pounds. The number of hour spent trolling dropped by 45% in 2012.

Fish Size: Average weight-per-fish from the cannery samples for albacore remained relatively stable through the years. The weight per fish for skipjack increased, yellowfin and wahoo remained the same, and bigeye slightly decreased

Revenues: Inflation-adjusted revenues for tunas increased in 2012, but decreased for non-tuna PMUS. Adjusted revenue for tunas increased by 23%, recovering from a slump in 2011 – the lowest adjusted revenue for tuna since 2000. Non-tuna adjusted revenues decreased by 44% from 2011. The adjusted revenue for tuna species peaked in 2002 at $21.5 million and peaked for non-tuna at $809,000 in 2006.

Bycatch: The 2012 longline bycatch by all boats totaled 31,930 fishes. 21% were tunas, 47% were non-tuna PMUS, and other pelagics and sharks accounted for 32%.

Plan Team Recommendations

There were no plan team recommendations for 2012.

Table 3. American Samoa 2012 estimated total landings of pelagic species by gear type

Species	Longline Pounds	Troll Pounds	Other Pounds	Total Pounds
Skipjack tuna	637,461	9,703	0	647,163
Albacore tuna	7,054,206	0	0	7,054,206
Yellowfin tuna	828,424	8,479	0	836,903
Kawakawa	0	144	289	433
Bigeye tuna	383,023	0	0	383,023
Tunas (unknown)	1,131	0	0	1,131
TUNAS SUBTOTALS	8,904,245	18,326	289	8,922,860
Mahimahi	22,645	157	0	22,802
Black marlin	4,615	0	0	4,615
Blue marlin	80,471	0	0	80,471
Striped marlin	16,306	0	0	16,306
Wahoo	187,851	597	0	188,448
Sharks (all)	7,150	7	0	7,157
Swordfish	31,179	0	0	31,179
Sailfish	3,333	0	0	3,333
Spearfish	2,852	0	0	2,852
Moonfish	7,507	0	0	7,507
Oilfish	454	0	23	478
Pomfret	977	0	0	977
NON-TUNA PMUS SUBTOTALS	365,339	760	23	366,123
Pelagic fishes (unknown)	385	0	0	385
OTHER PELAGICS SUBTOTAL	385	0	0	385
TOTAL PELAGICS	**9,269,968**	**19,086**	**313**	**9,289,367**

Interpretation: About 9.3 million pounds of pelagic species were landed by all methods in American Samoa during 2012. Longline fishing topped (99.8%) the pelagic landings. Albacore tuna comprised 79% of the tuna landings (76% of all pelagic landings), followed by yellowfin at 9%; bigeye, skipjack and unknown tunas comprised the rest of the total tuna landing. Wahoo topped the non-tuna PMUS all-methods total landings with 51%, followed by blue marlin, swordfish, and mahimahi.

Calculations: "Longline Pounds" total landing estimates are from the boat-creel survey for the alia longliners. These boat-creel survey landing estimates are augmented with longline logbook data from the larger longliners. The "Troll Pounds" category includes the pelagic landings of combined troll/bottomfishing trips as well as the landings of purely troll trips. The "Other

Pounds" category includes pelagic species not caught by longlining or trolling such as barracuda, rainbow runner and dogtooth tuna, caught with bottomfishing or spearfishing methods. In addition, the "All Sharks Species" categorizes all species of sharks that could and could not be identified by the fishermen.

Table 4. American Samoa 2012 estimated commercial landings, value and average price by pelagic species

	Longline			Troll		
Species	**Pounds**	**Value($)**	**Price($)/lb**	**Pounds**	**Value($)**	**Price/lb**
Skipjack tuna	637,461	$465,746	$0.73	8,811	$23,689	$3.26
Albacore tuna	7,054,206	$7,689,085	$1.09	0	$0	
Yellowfin tuna	828,424	$819,969	$0.99	8,315	$29,475	$3.54
Kawakawa	0	$0		321	$943	$2.93
Bigeye tuna	383,023	$478,778	$1.25	0	$0	
TUNAS SUBTOTAL	**8,903,113**	**$9,453,579**	**$1.06**	**17,447**	$59,106	**$3.39**
Mahimahi	6,291	$17,036	$2.71	122	$336	$2.75
Blue marlin	1,124	$1,231	$1.09	0	$0	
Striped marlin	952	$809	$0.85	0	$0	
Wahoo	187,851	$170,580	$0.91	280	$917	$3.28
Sharks (all)	0	$0	$	7	$3	$0.50
Swordfish	2,344	$5,561	$2.37	0	$0	
NON-TUNA PMUS SUBTOTAL	**198,562**	**$195,218**	**0.98**	**409**	**$1,257**	**$3.08**
PELAGICS TOTALS	**9,101,675**	**$9,648,796**	**1.06**	**17,856**	**$60,363**	**$3.38**

Interpretation: About 9.1 million pounds of tuna and non-tuna PMUS species by all methods are estimated to have been sold in 2012, which is estimated to be 98% of the estimated total pelagic landings, earning an estimated revenue of $9.7 million.

Calculation: Estimated commercial landings, value, and price per pound calculations are the same as those described for Table 3 and in greater detail in the Fishery Data History section above. The Troll/Non-Longline category in Table 3 includes pelagic species not caught by longlining such as barracuda, rainbow runner and dogtooth tuna, that were caught with bottomfishing or spearfishing methods.

Table 5. Longline effort by American Samoan vessels during 2012

Trips	195
Sets	4,208
Hooks x 1000	12,109
Lightsticks	1,272

Table 6. Number of fish kept, released and percent released for all American Samoa longline vessels during 2012

Species	Number Kept	Number Released	Percent Released
Skipjack tuna	46,614	5,380	10%
Albacore tuna	178,774	508	0%
Yellowfin tuna	13,907	684	5%
Bigeye tuna	7,491	335	4%
Tuna unknown	63	17	21%
Tunas subtotals	**246,849**	**6,924**	**3%**
Mahimahi	1,046	379	27%
Black marlin	41	3	7%
Blue marlin	592	1,188	67%
Striped marlin	237	188	44%
Wahoo	6,169	1,774	22%
Sharks (all)	110	6,932	98%
Swordfish	245	68	22%
Sailfish	47	314	87%
Spearfish	62	901	94%
Moonfish	153	463	75%
Oilfish	24	9,891	100%
Pomfret	111	893	89%
Non-tuna PMUS subtotals	**8,837**	**22,994**	**72%**
Pelagic fishes (unknown)	8	3,441	100%
Other pelagic subtotals	**8**	**3,441**	**100%**
TOTAL PELAGICS	**255,694**	**33,359**	**12%**

Interpretation: Table 5 lists 25 vessels landed pelagic species in American Samoa during 2012. The vessels conducted 195 fishing trips deploying 4,208 longline sets, using 12.1 million hooks and 1,272 lightsticks. Table 5 values are used to calculate average trip, set, hooks etc. for each longline vessel based in American Samoa.

7.8 trips and 168 sets were made per boat
484,360 hooks and 51 lightsticks were used per boat
2883 hooks were used per set

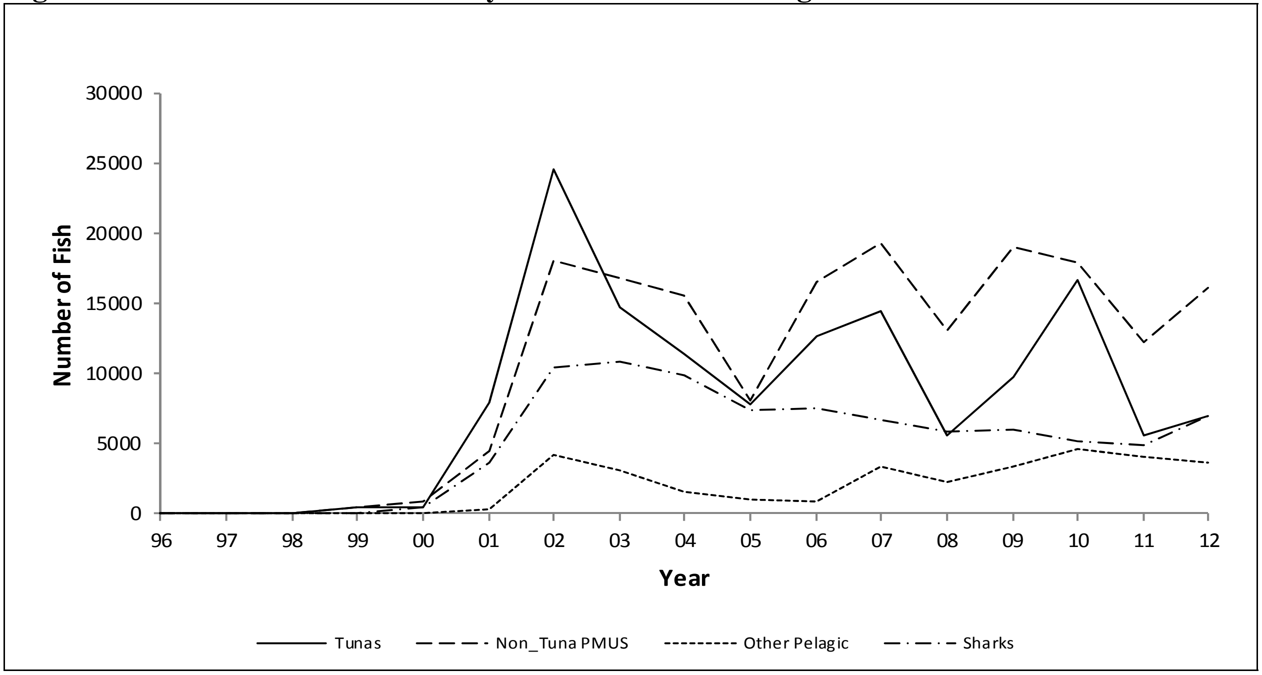
More than 255,000 pelagic species were caught, of which 12% were released by the longline fishery during 2012.

Tuna species accounted for about 21% of total releases, while non-tuna and other pelagic made up 79%. Oilfish, sharks, blue marlins and unknown pelagics topped the list of released species.

Fish can be released for various reasons including quality, handling and storage difficulties, and marketing problems. Investigation into the reasons for releasing of pelagic species are recommended because of the high release rate for many non-tuna PMUS and releases of some tuna.

Calculation: These values are sums or the number of fish kept and the number of fish released from Longline Logbook data for all of the longline vessels in Samoa. The percent released is calculated as the number released divided by the sum of the number released and the number kept. The percentages for subtotals and totals are the sum of released species for the subtotal or total divided by the sum of kept plus the sum of released for the subtotal or total. The kept values for sharks include those that were finned. All species of sharks entered in the Longline Logs are combined in the All Sharks species. Rays and Sunfish are included in the Misc Pelagic Fish species. A completed trip is denoted when a vessel makes a landing within a given calendar year.

Figure 2. Number of fish released by American Samoa longline vessels



Interpretation: The number of sharks released over the years has declined from 10,831 to 3,572 between 2003 and 2012. Tuna released in 2012 is higher than 2011, but is the third lowest since 2001. Non-tuna PMUS released also increased.

Calculation: These values are sums of Longline Logbook number released data for each year. They are summed according to the species groups in Table 3 with Sharks separated out of the "Non-Tuna PMUS" species group.

Year	Tunas	Non-Tuna PMUS	Sharks	Other Pelagics
1996	0	0	37	0
1997	50	36	19	1
1998	71	29	28	0
1999	492	438	37	43
2000	371	815	386	0
2001	7,888	4,457	3,648	239
2002	24,601	18,100	10,459	4,183
2003	14,679	16,826	10,831	3,125
2004	11,323	15,481	9,918	1,521
2005	7,830	8,039	7,318	1,057
2006	12,609	16,498	7,487	842
2007	14,418	19,350	6,667	3,308
2008	5,542	13,039	5,833	2,274
2009	9,698	19,022	5,930	3,291
2010	16,695	17,935	5,108	4,575
2011	5,567	12,161	4,035	4,835
2012	6,924	16,062	3,572	6,932

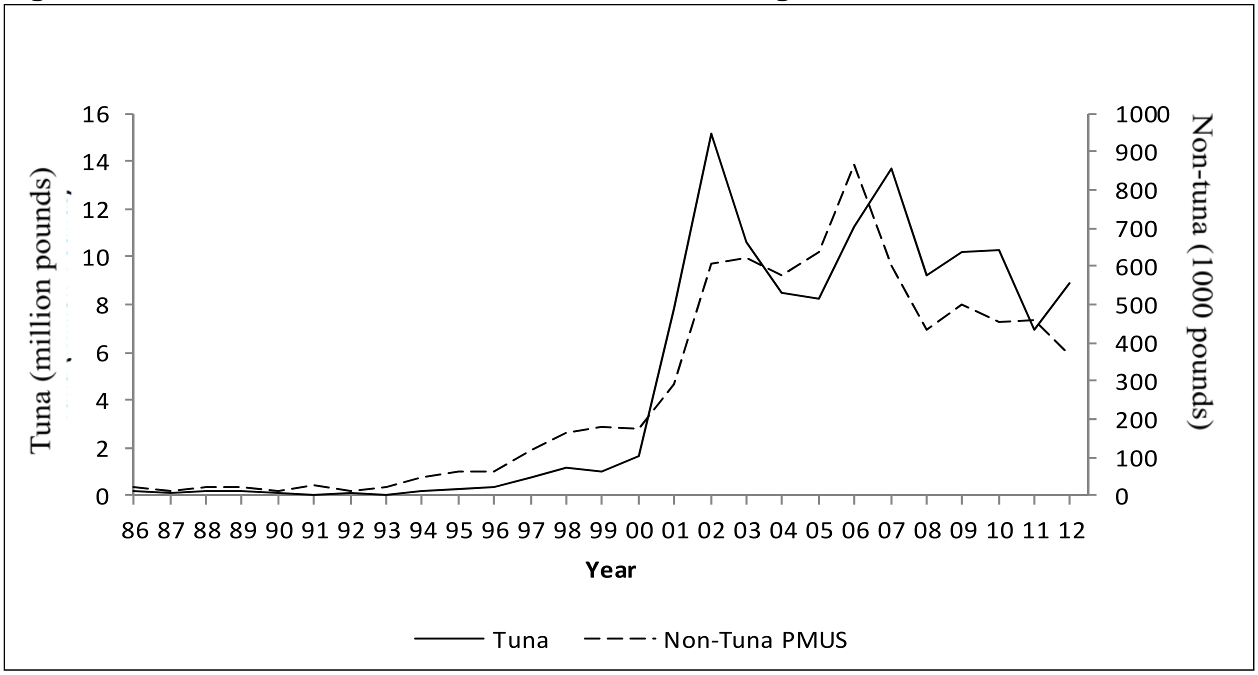
Table 7. American Samoa 2012 trolling bycatch

Bycatch							Interviews		
Catch	**Alive**	**Injured**	**Dead**	**Unknown**	**Total**	**%BC**	**BC**	**All**	**%BC**
1527	0	0	0	0	0	0	0	59	0

Interpretation: There was no bycatch recorded for 2012 from trolling only; 59 interviews were conducted with 1,527 pelagic fish landed. Using fishermen's reports at the dock may not accurately reflect the number of fish returned at sea.

Calculation: The trolling bycatch table is obtained from creel survey interviews. The bycatch numbers are obtained by counting fish on interview forms for purely troll trips with a disposition of bycatch. Bycatch is reported by fishermen when interviewed at the landing site in response to questions from the data collector; bycatch are fish thrown back at sea by the fishermen. The catch for all species is included for comparison and is obtained by counting all fish listed on the same interview forms. The number of interviews is a count of the purely trolling interview forms.

Figure 3. American Samoa annual estimated total landings of tuna and non-tuna PMUS



Interpretation: Total tuna landings increased 23% in 2012 from the lowest seen since 1997. Non-tuna (PMUS) declined in 2012 by 22% after a steady trend from 2008 through 2011.

Calculation: Estimated total landings for Tunas and Non-Tuna PMUS were calculated by summing the total landings for the species in these categories as defined by Table 3.

Table 8. American Samoa annual estimated total landings (lbs) of tuna and non-tuna PMUS from 1986 through 2012

Year	Tuna	Non Tuna PMUS
1986	190,967	23,899
1987	144,037	10,894

Figure 4. American Samoa annual estimated total mahimahi landings by gear

Interpretation: Estimated landings of mahimahi by longline gear increased by 4% to 22,138 lbs in 2012. Longline gear landed more mahimahi than trolling. Trolling mahimahi landings decreased in 2012 by 43% from 2011.

Calculation: The estimated total annual landings of mahimahi are listed for longline and trolling fishing methods as explained in Table 3.

Table 9. American Samoa annual estimate total mahimahi landings (lbs) by gear

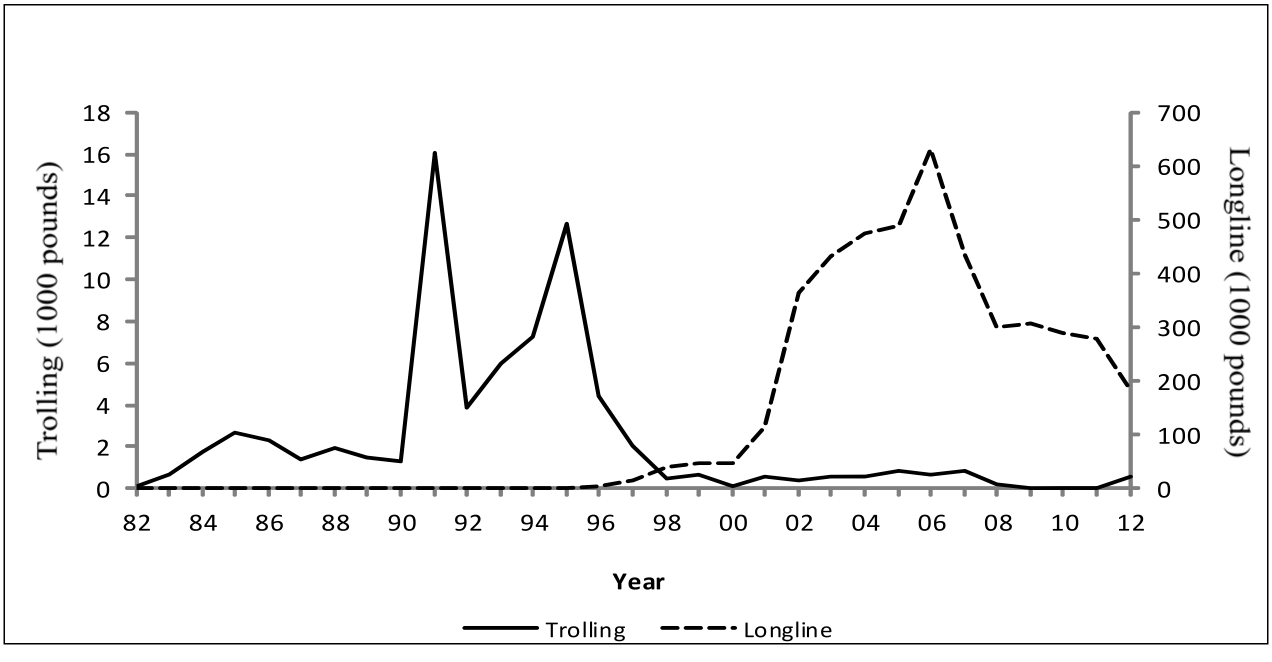
Figure 5. American Samoa annual estimated total wahoo landings (lbs) by gear



Interpretation: Estimated landings of wahoo showed an increasing trend from 1999 and peaked in 2006; landings gradually decreased from 2007 to 2012. Longline gear landed more wahoo. 2012 longline landings decreased by 34% from 2011, while troll landings increased by 985% to 597 lbs from a low of 55 lbs in 2011.

Calculation*:* The estimated total annual landings of wahoo are listed for longline and trolling fishing methods as explained in Table 3.

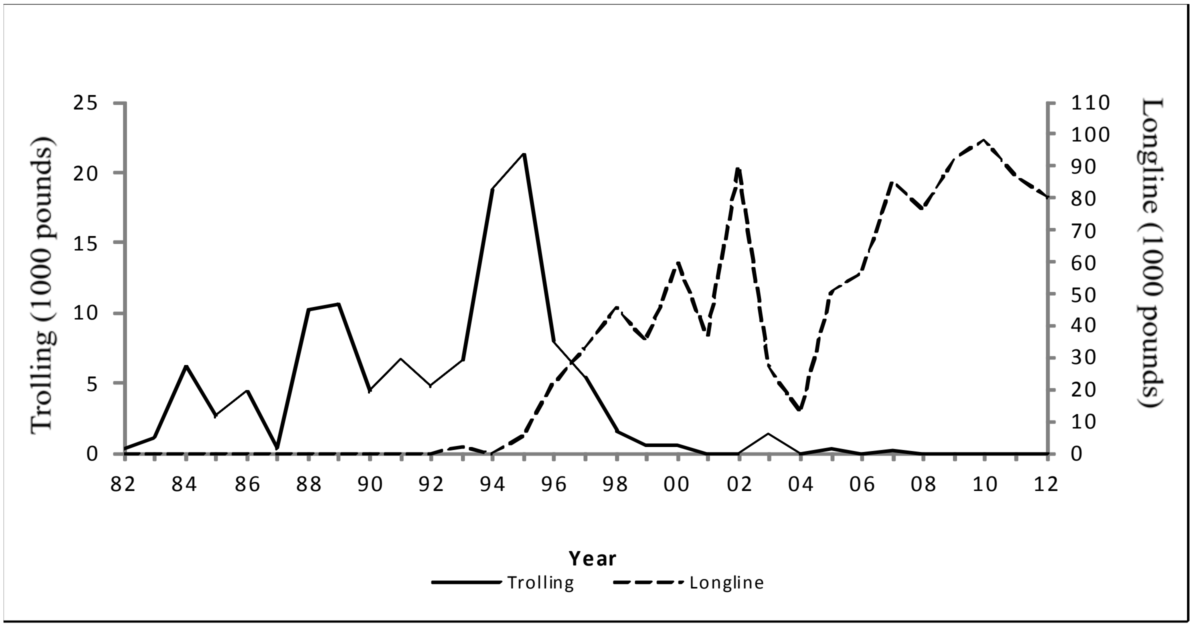
Figure 6. American Samoa annual estimated total blue marlin landings (lbs) by gear



Interpretation: Estimated blue marlin landings for longline and trolling gears total 79,927 pounds, with longline comprising 100% of the landings. 2012 longline landing decreased by 7% from 2011, while troll landings remained the same at zero.

Calculation: The estimated total annual landing of blue marlin is listed for longline and trolling fishing methods as explained in Table 3. The average and standard deviation for the Longline Method is calculated from 1993 onward.

Table 11. American Samoa annual estimated total blue marlin landings (lbs) by gear

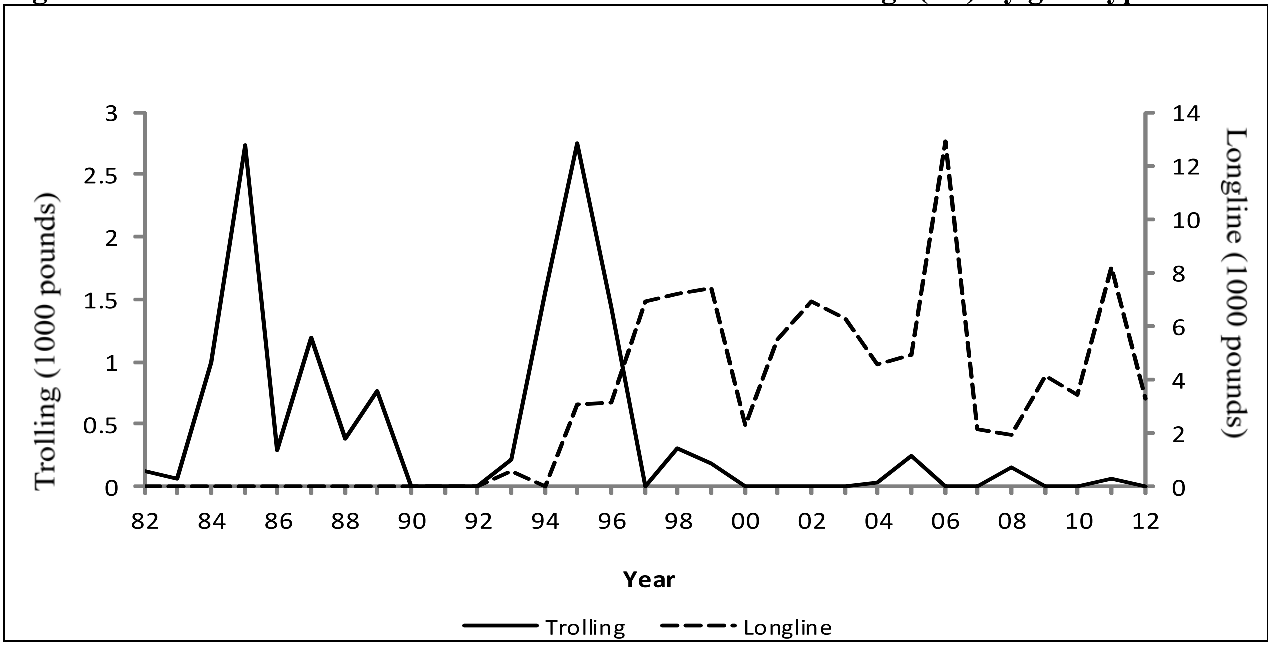
Figure 7. American Samoa annual estimated total sailfish landings (lbs) by gear type



Interpretation: Estimated landings of sailfish by longline gear decreased by 60% to 3,262 pounds in 2012. Troll landings returned to zero, which is consistent from 1997 through 2012.

Calculation: The estimated total annual landings of sailfish are listed for longline and trolling fishing methods as explained in Table 3.

Table 12. American Samoa annual estimated total sailfish landing (lbs) by gear type

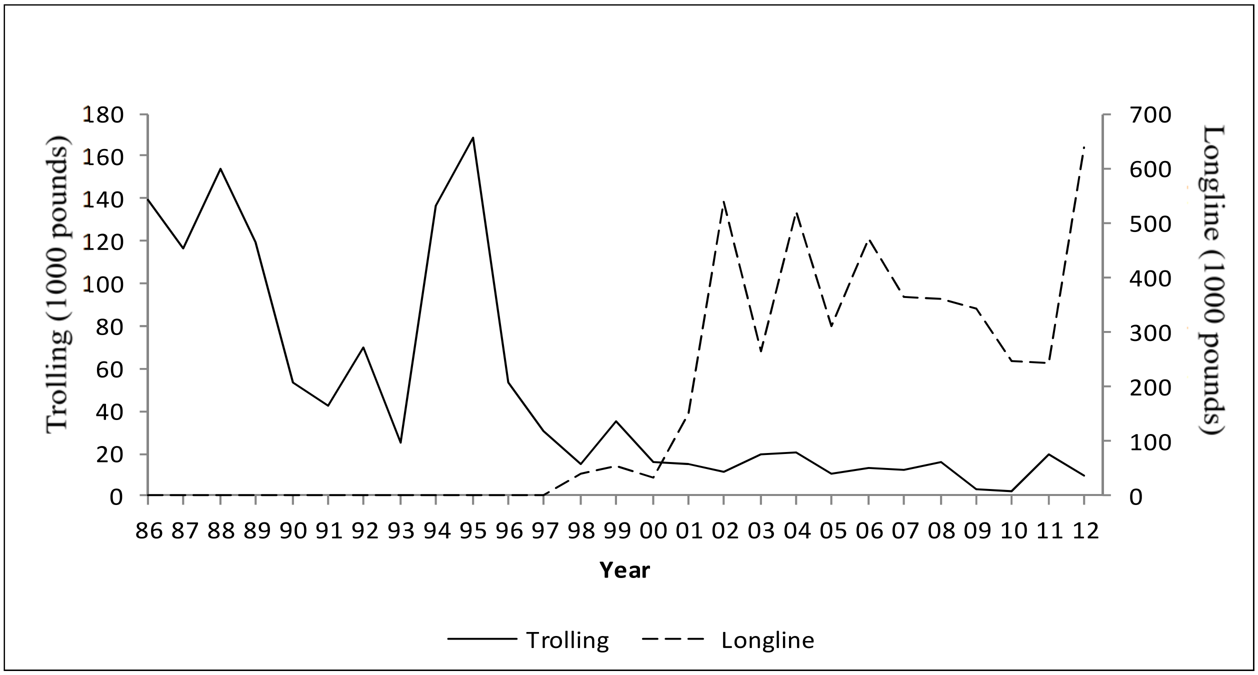
Figure 8. American Samoa annual estimated total skipjack tuna landings (lbs) by gear type



Interpretation: Estimated 2012 longline landings of skipjack tuna increased by 162% to 637,461 pounds. Estimated troll landings decreased by 51%.

Calculation: The estimated total annual landings of skipjack tuna are listed for longline and trolling fishing methods as explained in Table 3.

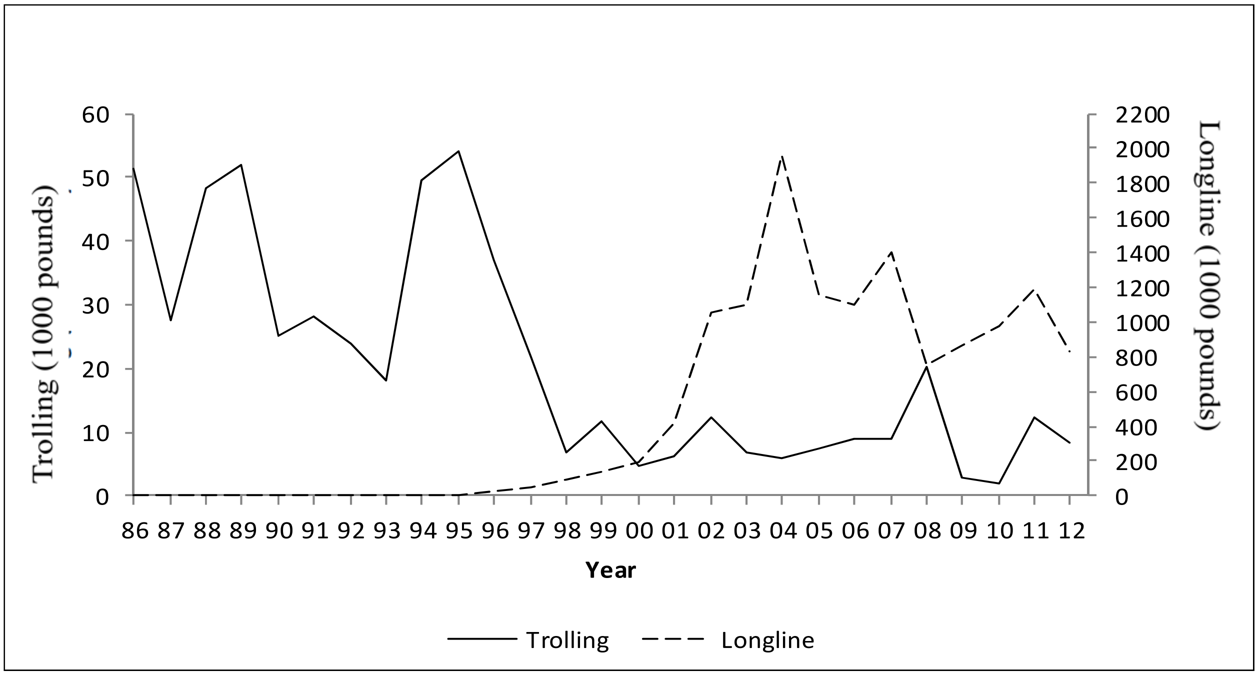
Figure 9. American Samoa annual estimated total yellowfin tuna landings (lbs) by gear



Interpretation: Estimated landings of yellowfin tuna decreased in both fisheries in 2012. Troll landing decreased 30% and longline landings decreased 32%.

Calculation: The estimated total annual landings of yellowfin tuna are listed for longline and trolling fishing methods as explained in Table 3.

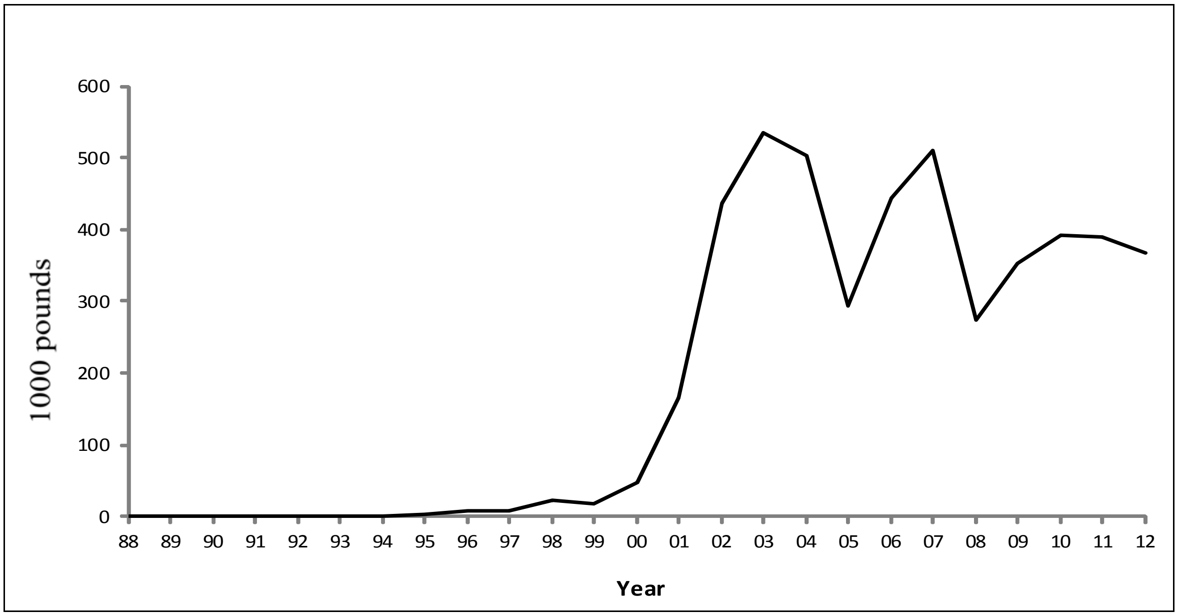
Figure 10. American Samoa annual estimated total bigeye tuna landings (lbs) by longlining



Interpretation: Estimated total longline landings of bigeye tuna shows an increasing trend from 2008 to 2010, but started decreasing in 2011, dropping another 2% in 2012.

Calculation: The estimated total annual landings of bigeye tuna is listed for longline fishing method as explained in Table 3. The average and standard deviation for the pounds caught is calculated from 1991 onward.

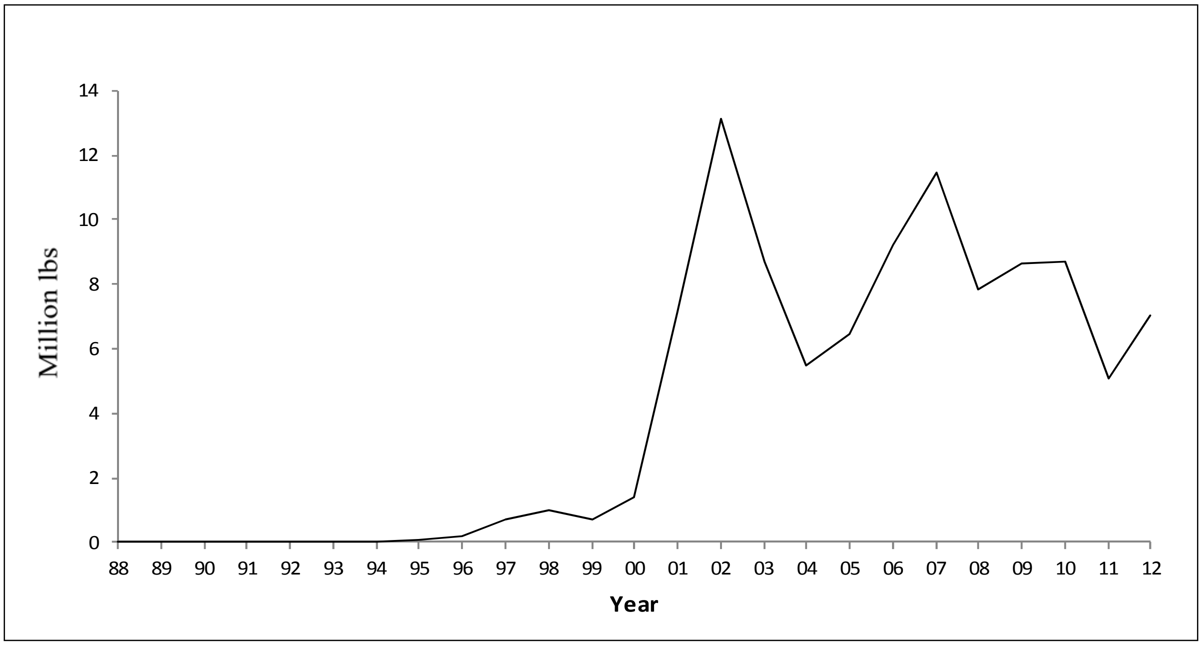
Figure 11. American Samoa annual estimated total albacore landings (lbs) by longlining



Interpretation: Estimated total albacore landings in 2012 increased by 38% to 7.0 million pounds from 2011. The landings varied from 5 million pounds to 13 million pounds between 2002 and 2012. The 2002 albacore landings estimate of 13.1 million pounds is the highest ever recorded in the history of the fishery. Since the longline fishery initially began, it has been the most commonly used method of fishing for pelagic species, especially for albacore tuna.

Calculation: The estimated total annual landings of albacore tuna is listed for the longline fishing methods. The average and standard deviation is calculated from 1988 onward.

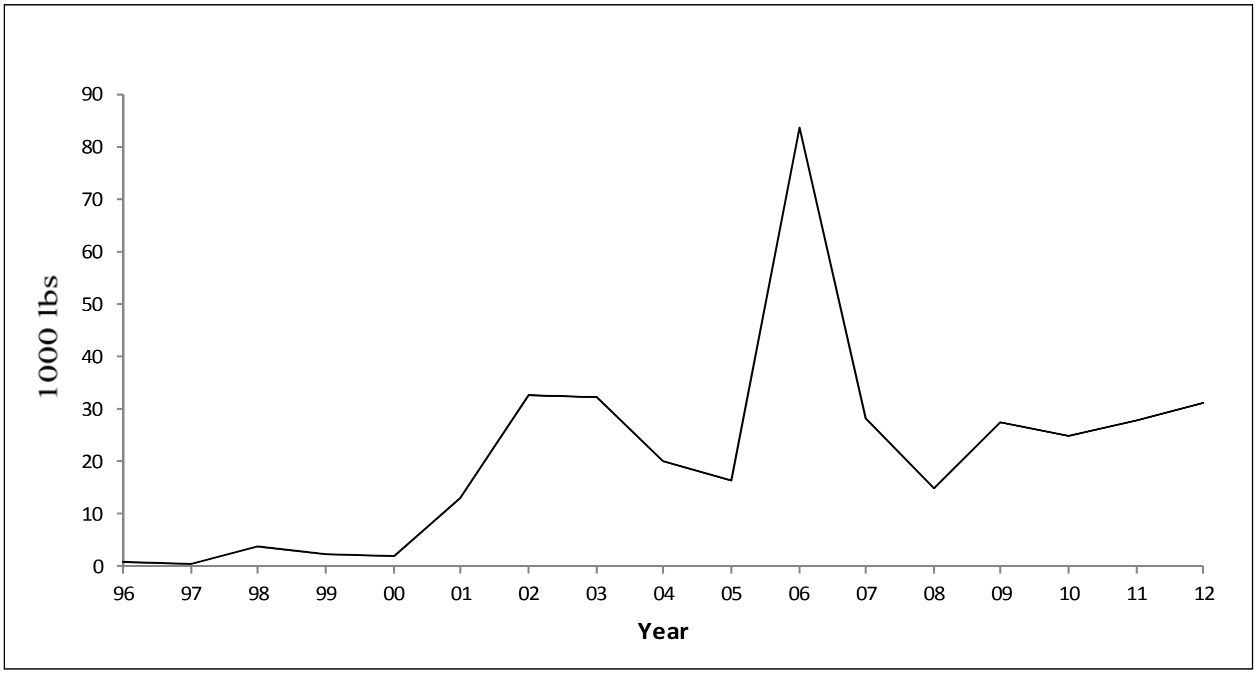
Figure 12. American Samoa annual estimated total longline swordfish landings in pounds



Interpretation: More than 31,000 pounds of swordfish are estimated to have been landed in American Samoa in 2012, which is 11% more than 2011. The 2006 landings are the highest for this fishery; landings declined in 2007 and 2008 before it returned to 2002-2003 levels from 2009-2012.

Calculation: The estimated total annual landings of swordfish are listed for longline and trolling fishing methods as explained in Table 3.

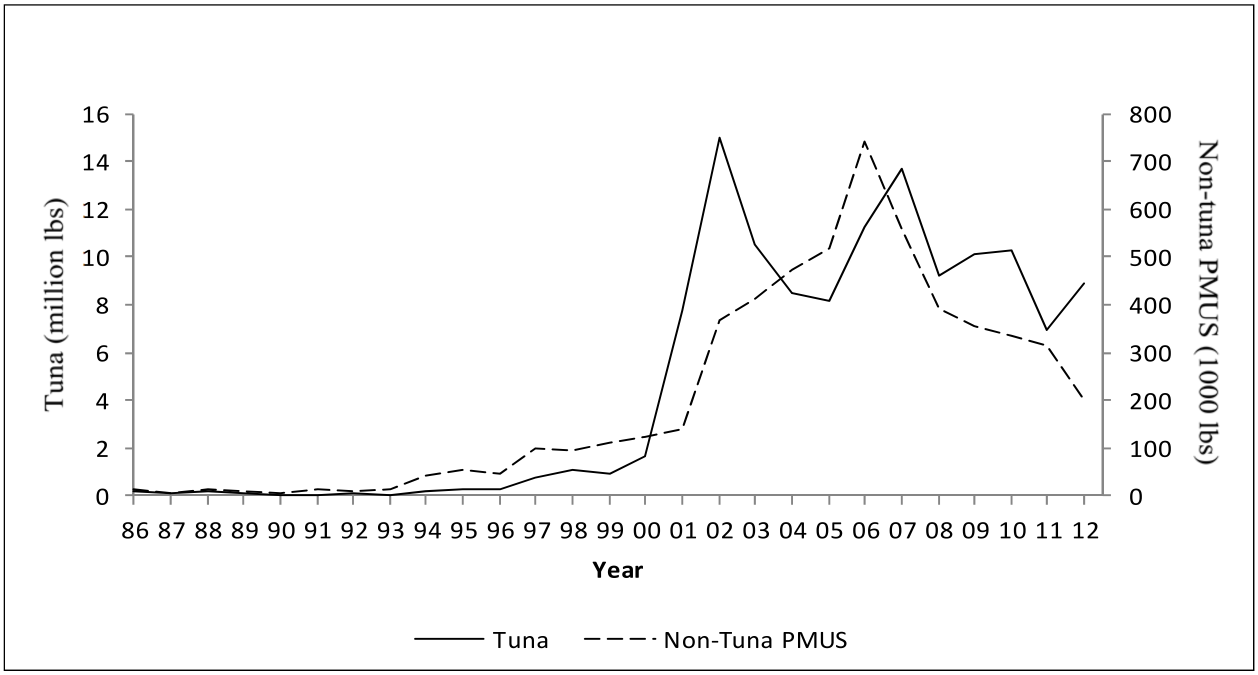
Figure 13. American Samoa annual commercial landings of tunas and non-tuna PMUS



Interpretation: The estimated total commercial landing in 2012 is about 8.9 million pounds. Landings for tuna increased 28% in 2012 from the 2011 estimate of approximately 6.9 million pounds. The commercial landings of non-tuna (PMUS) decreased by 37% from 2011 landings.

Calculation: Estimated commercial landings for Tunas and Non-Tuna PMUS were calculated by summing the commercial landings for the species these categories as defined by in Table 3.

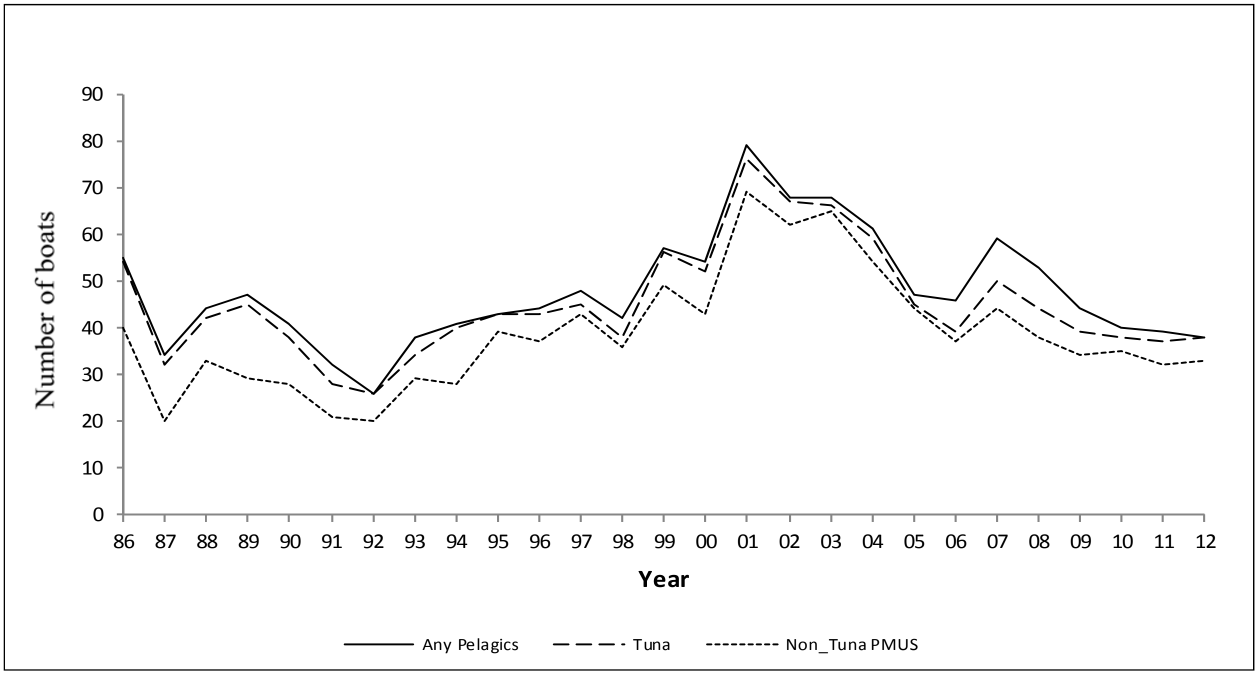
Figure 14. Number of American Samoa vessels landing any pelagic species, tunas and non-tuna PMUS



Interpretation: There were 38 vessels in American Samoa vessels landing pelagic species in 2012. Boats landing tuna species equaled 38, and 33 boats landed non-tuna PMUS. The highest number of boats landing any pelagic, tuna and non-tuna PMUS species was 79, 76, and 69 respectively during 2001. Since the peak in 2001, the number of American Samoan vessels landing any pelagic, tuna and non-tuna species has declined. There was a brief increase in the number of vessels in 2007 and 2009 to 59 and 53, respectively, but in 2009 the downward trend was resumed with yet another 3% drop in 2012.

Calculation: Prior to 1997, each boat counted in the Any Pelagics column made at least one landing in an offshore creel survey interview of at least one species in Table 4 in the given year. Likewise each boat counted in the other two columns made at least one landing in an offshore creel survey interview of at least one species in the corresponding subgroup of Table 3 in the given year. In 1997 and after, the count of non-interviewed boats that made at least one landing of the appropriate species in a longline log was added to the count of interviewed boats from the offshore creel survey.

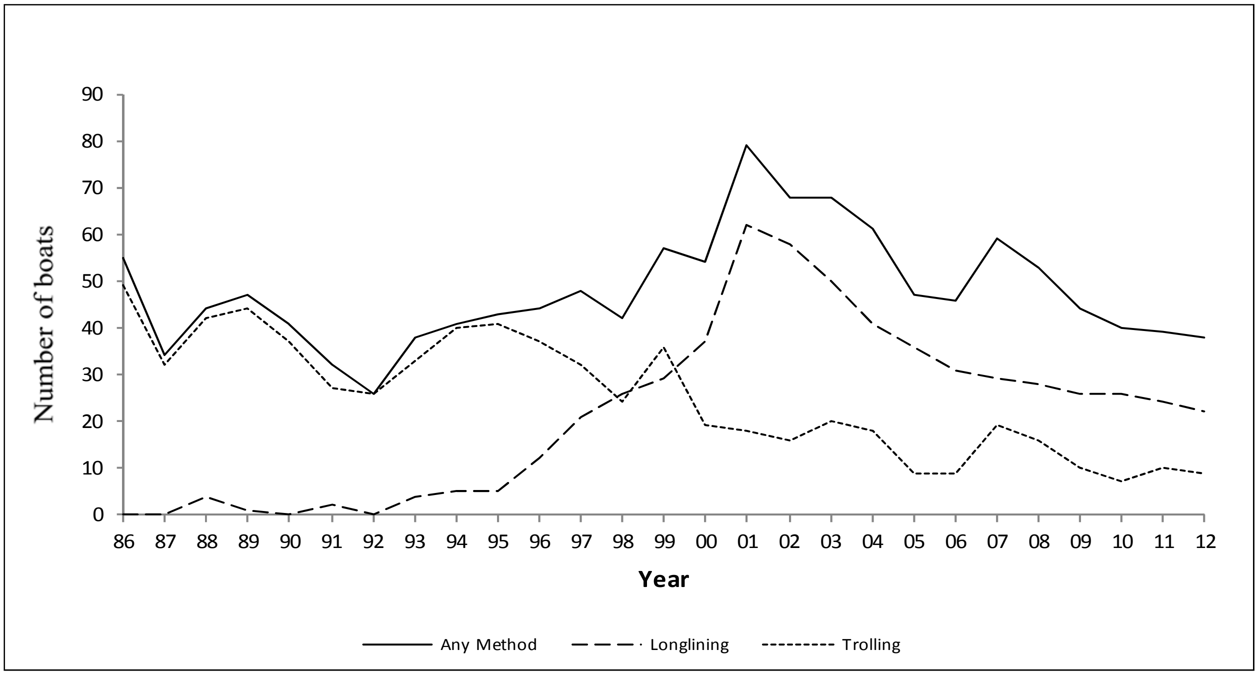
Figure 15. Number of American Samoa boats landing any pelagic species by longlining, trolling and all methods



Interpretation: The number of American Samoan vessels landing pelagic species in 2012 using any method was 38. There were 22 boats using longline gear and 9 boats using troll gear. The number of longline boats decreased by two and number of boats using trolling decreased by one boat.

The number of American Samoan vessels using any method and longline gear have been declining over the years since the peak in 2001.

Calculation: Prior to 1997, each boat counted in the Any Method column made at least one landing in an offshore creel survey interview of at least one species in Table 4 in the given year. Each boat counted in the Longlining and Trolling columns made at least one landing in an offshore creel survey interview of at least one species in Table 4, using the longline or troll or combined troll/bottom fishing methods in the given year. In 1997 and after the count of non-interviewed boats that made at least one landing of the species in Table 4 in a longline log during the given year was added to the count of interviewed boats from the offshore creel survey in the Any Method and Longlining columns. The average and standard deviation for the number of boats using Longlining is calculated from 1988 onward.

Figure 16. Number of permitted and active longline fishing vessels in the A (≤ 40 foot) and D (> 70.1 foot) size classes

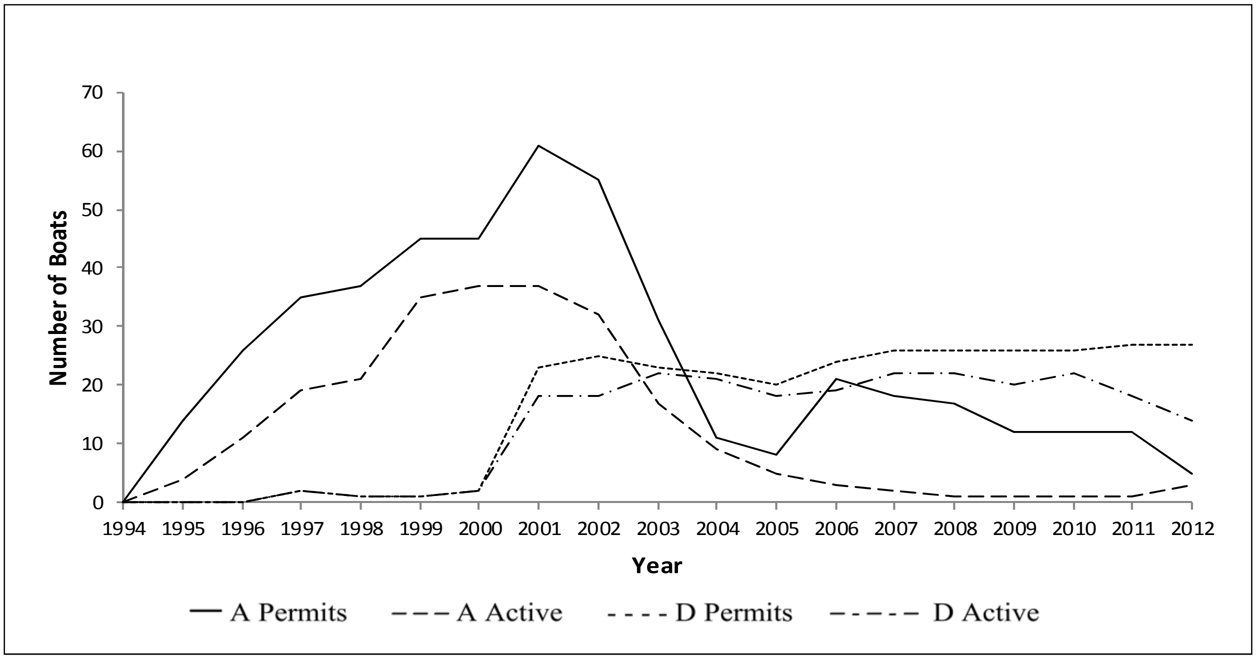

Figure 17. Number of permitted and active longline fishing vessels in the B (40.1 to 50 foot) and C (50.1 to 70 foot) size classes

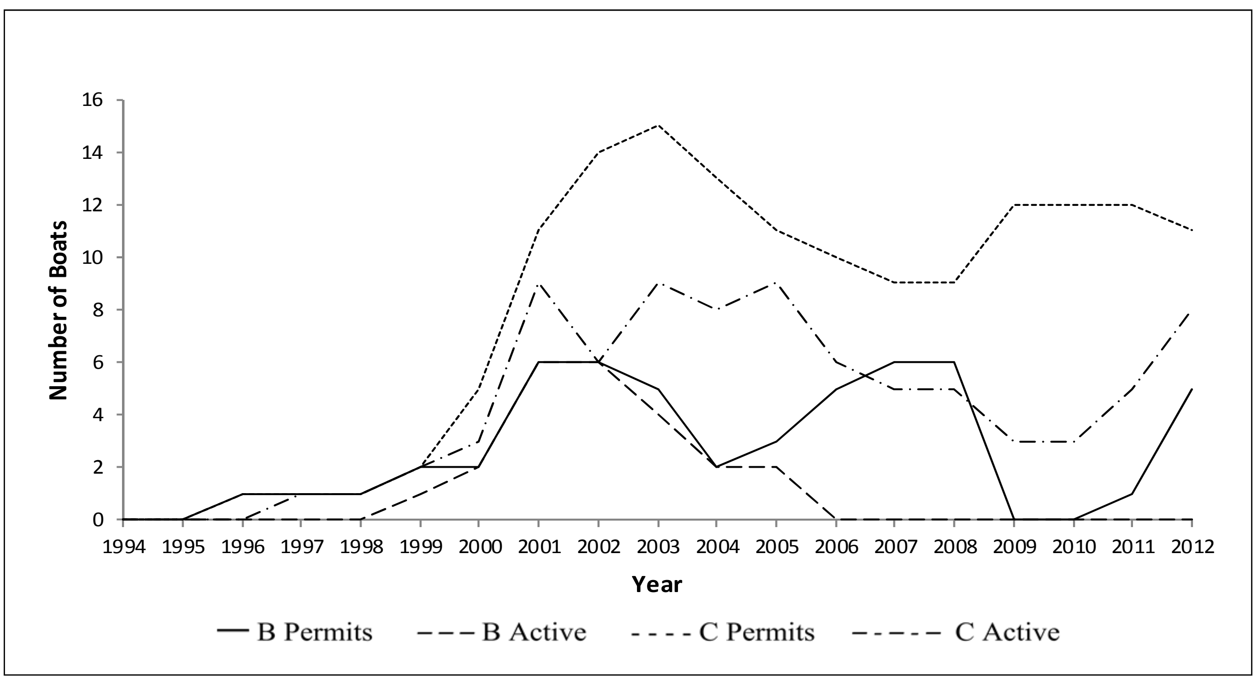

Interpretation: In 2012, three alias (Class A) out of the 5 permitted vessels were active. The use of alias has steadily declined since 2001 when 37 alias were active, although 2012 saw an increase of two more vessels. Five Class B permits were issued in 2011, but no vessels from this class were active. Eight of 11 Class C permitted vessels were active. Class D boats dominated the American Samoa longline fishery in 2012, with 14 of 27 permitted vessels making landings. However, the number of Class D vessels making landings decreased by 22% in 2012.

Calculation: For 2006, the number of permits is the number actual of Limited Entry Longline Permits issued for each size class late in 2005. For earlier years, the number of permits is the number of federal general longline permits issued for each vessel size category. For the C and D size classes the number of permits may include those for Hawaiian permitted boats landing their fish in American Samoa. The number of active boats is those that have submitted longline logs or have been interviewed in the boat-based creel survey after a longline fishing trip during the year. Boats in the boat-based creel survey are not counted as active if they are interviewed using only fishing methods other than longlining such as bottomfishing or trolling.

The range of dates that constitutes a year of activity is skewed to be in line with when the longline permits are issued and expire, roughly Feb. 25th. The active year of 1996 is from February 25, 1996 to February 24 1997. This applies through 2004. The active year 2005 is from February 25, 2005 to December 31, 2005. The active year of 2006 is the calendar year; the active year of 1995 is January 1, 1995 to February 24, 1996. This causes the number of active vessels to be slightly different from other counts of longline vessel activity based on the calendar year.

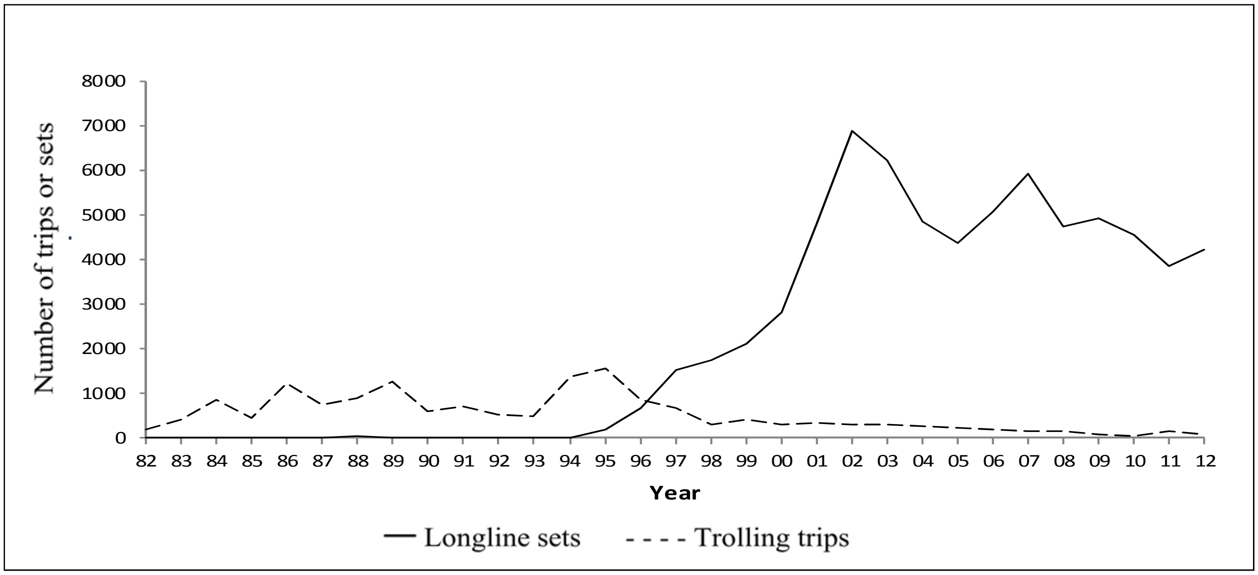
2012	5	3	5	0	11	8	27	14

Figure 18. Number of American Samoa troll trips and longline sets for all pelagic species by method



Interpretation: Longline sets increased by 9% in 2012, which reversed a declining trend. Longline sets varied from 3,800 to 6,800 sets between 2002 and 2011. The 2012 estimated number of troll trips decreased by 40% from 2011.

Calculation: The number of Troll Trips is calculated by first subtracting the total longline pounds of Table 1 from the total pounds to get an estimate of the number of pounds caught by trolling and other fishing methods. This value is divided by the catch per hour for pure troll trips, from the offshore creel survey system expansion, to get the number of trolling hours. The number of trolling hours is then divided by the hours per trip for a purely trolling trip from the offshore creel survey system expansion to get the number of troll trips.

The number of longline sets using logbook data is obtained by counting all of the sets entered in the longline logbook system for the given year for interviewed and non-interviewed boats.

Prior to 1997, the number of longline sets using creel survey data is the expanded number of longline fishing trips from the offshore creel survey system. In 1997 and after this number is the expanded number of longline fishing trips from the offshore creel survey system for interviewed vessels plus the count of all of the sets entered in the longline logbook system for non-interviewed vessels. The average and standard deviation for Longline Sets from logbook data and creel data is calculated from 1996 onward for comparison.

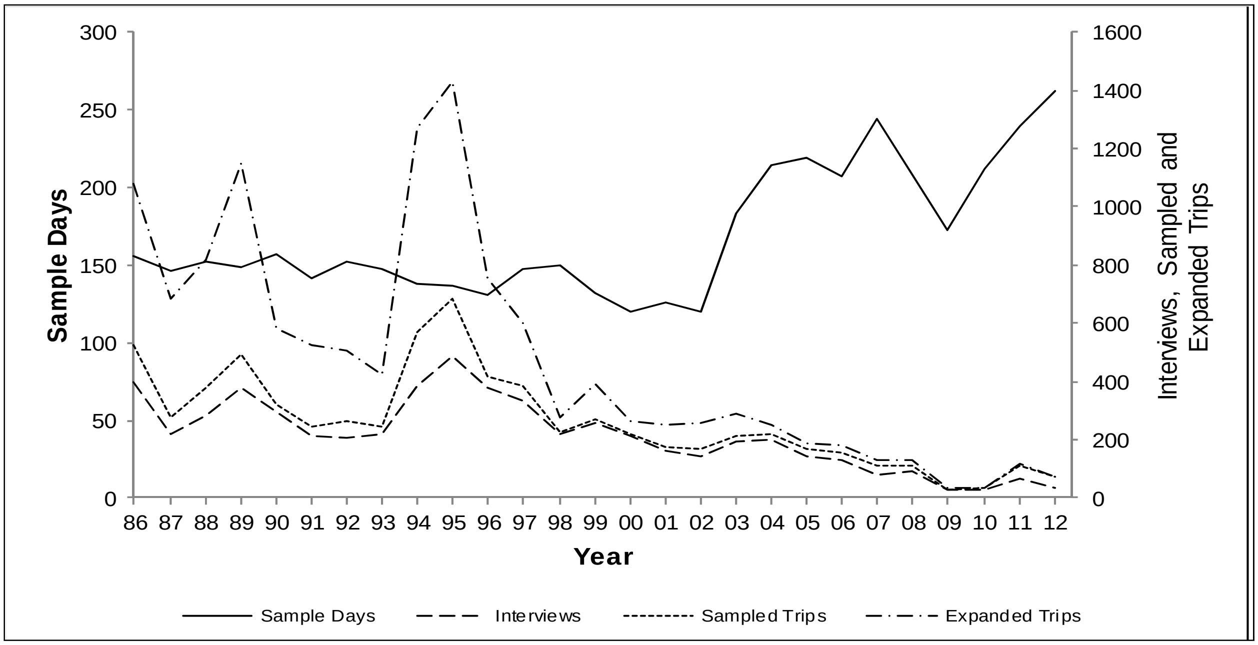
Figure 19. Number of American Samoa sample days, trolling interviews, and trolling trips



Interpretation: Sample days increased by 10% to 262 in 2012 but trolling interviews decreased by 45% to 37. Trolling trips sampled increased by 6 in 2010 and spiked in 2011, but has overall been experiencing a declining trend since a high of 683 in 1995.

Calculation: All data in this table and chart comes from the Tutuila and Manua Boat-Based Creel Survey. The number of Sample Days is the number of weekend/holiday and weekday sample days in the Tutuila Boat-based Creel survey for the year. The number of Trolling Interviews is the number of Tutuila pure trolling interviews without pooling plus the number of unadjusted Manua pure trolling interviews for the year. The number of Sampled Trips is the number of pure trolling trips actually counted in the Tutuila and Manua surveys. The Expanded Number of Trips is the expanded number of Tutuila pure troll trips plus the number of Manua troll trips adjusted for the coverage factor.

Table 21. Number of American Samoa sample days, trolling interviews, and trolling trips

Year	Sample Days	Trolling Interviews	Trolling Sampled	Trips Expanded	Percent

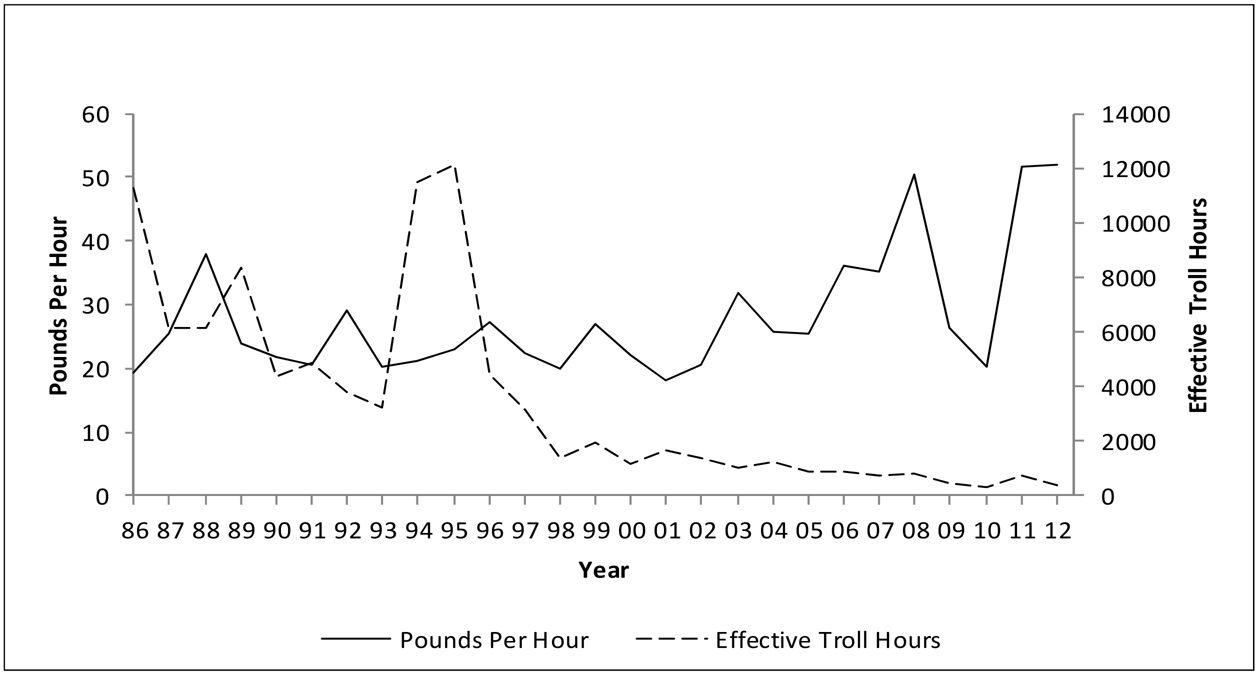
Figure 20. American Samoa pelagic catch per hour of trolling and number of trolling hours.



Interpretation: Catch per hour of trolling in 2012 increased by 0.9% to 52 from 51.6 lbs in 2011. The number of troll hours decreased in 2012 by 45%. The troll hours in 2012 are similar to those seen from 2009 to 2010.

Calculation: For purely trolling trips where the number of hours was recorded, the total catch was divided by the total number of trolling hours to obtain CPUE.

The number of effective Trolling Hours is calculated by first subtracting the total longline pounds of Table 3 from the total pounds to get an estimate of the number of pounds caught by trolling and other fishing methods. This value is divided by the catch per hour for pure troll trips, from the offshore creel survey system expansion, to get the number of trolling trip-hours.

Table 22. American Samoa pelagic catch per hour of trolling and number of trolling hours

Year	CPUE	Hours
1982	25.91	1,019

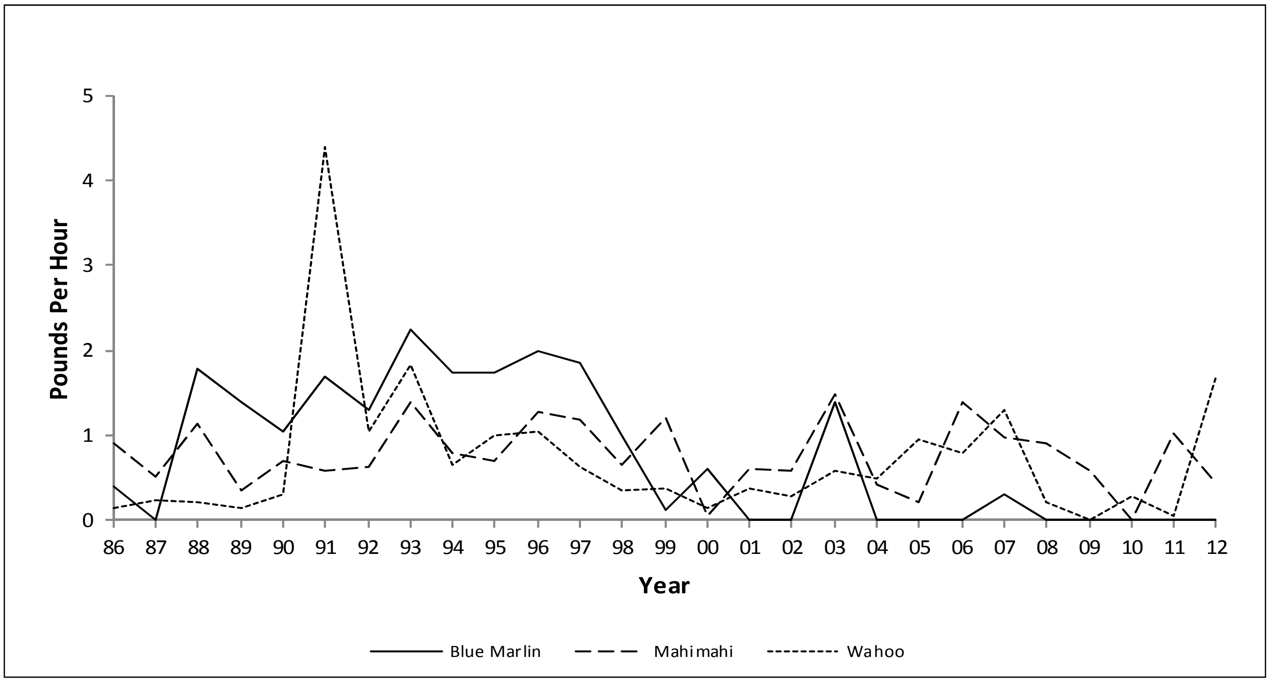
Figure 21. American Samoa trolling CPUEs (lbs per hour fished) for blue marlin, mahimahi, and wahoo



Interpretation: CPUE (pounds caught per trolling hour) for blue marlin are zero for 2012. For blue marlin this is the same as the last four consecutive years. CPUE for mahimahi in 2012 decreased by 57% to 0.44 from 1.04 in 2011. For wahoo, CPUE increased to 1.67 pounds per hour from 0.04 in 2011.

Calculation: The values for each of the three species is obtained by dividing the Troll Pounds for each species in Table 3 by the expanded number of trip-hours for purely trolling trips from the offshore creel survey system.

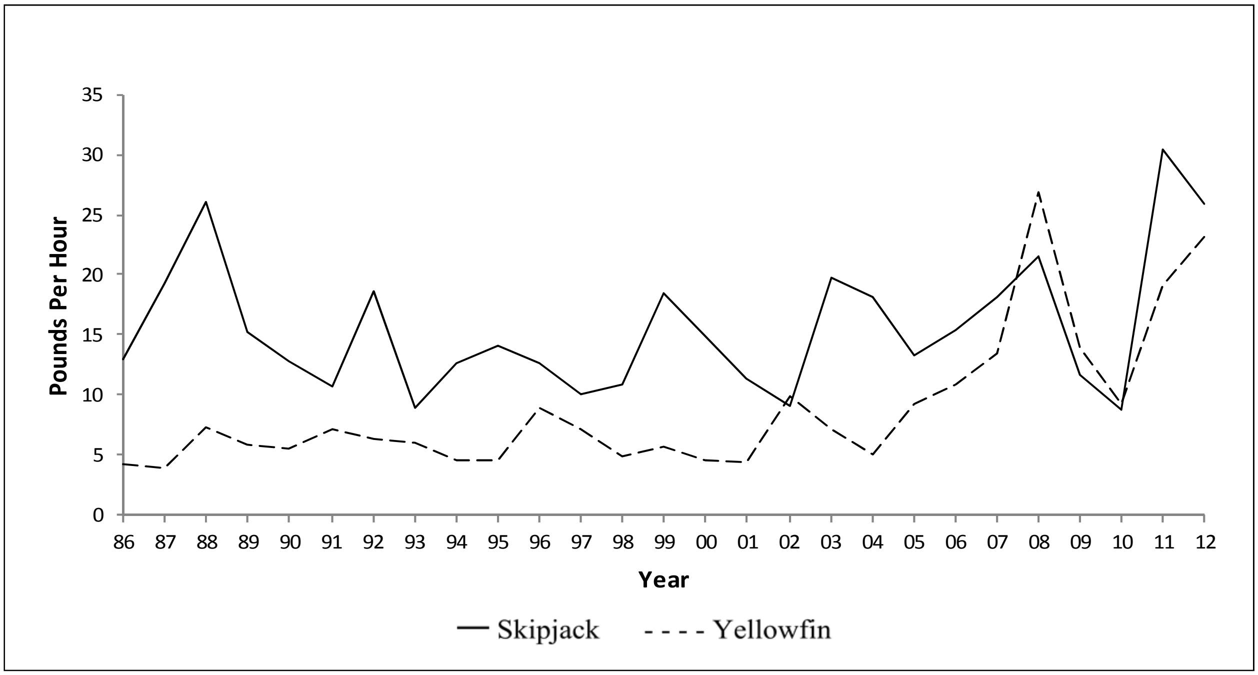
Figure 22. American Samoa trolling CPUEs for skipjack and yellowfin tuna in pounds per hour fished



Interpretation: The 2012 total pounds for skipjack decreased by 15% to the third highest rate per troll hour in its history. Estimated 2012 troll CPUE for yellowfin increased by 21%.

Trolling regularly occurs closer to the islands of American Samoa, at different times, and targets different depths than longline fishing.

Calculation: The values for each of the two species is obtained by dividing the Troll Pounds for each species in Table 3 by the expanded number of trip-hours for purely trolling trips from the offshore creel survey system.

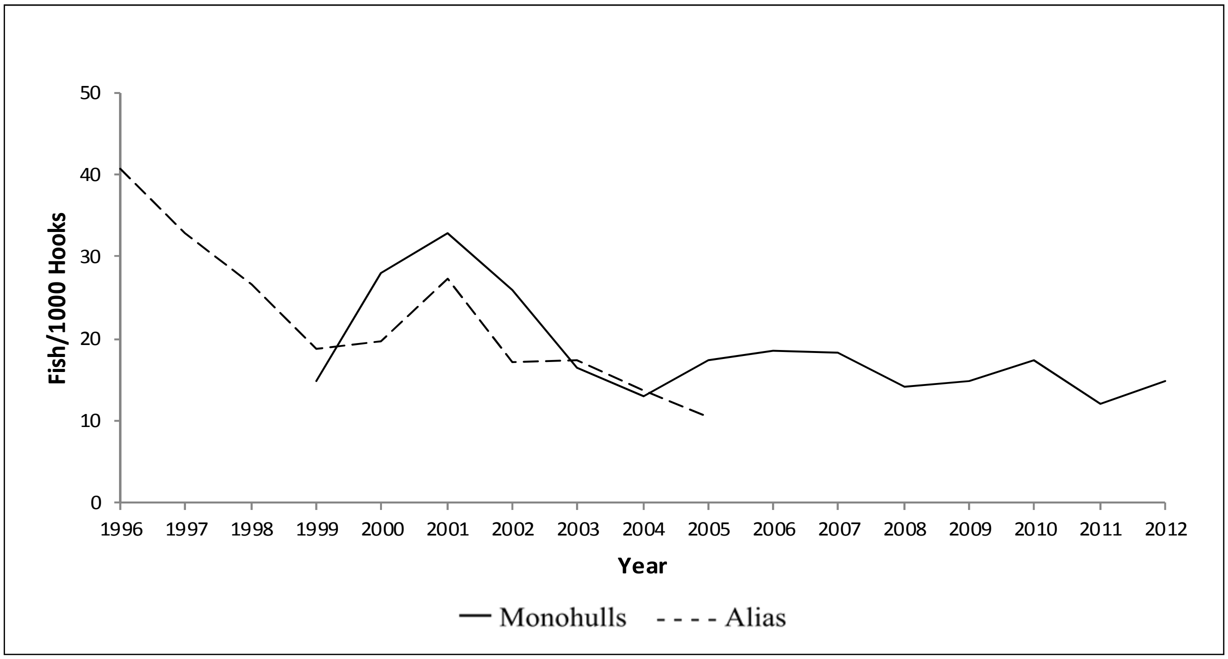
Figure 23. American Samoa longline albacore tuna CPUE for alias and mono-hull vessels based on longline logbook data



Interpretation: Due to fishery data confidentiality, albacore information for alias from 2006 through 2012 is omitted. Monohulls catch rate in 2012 was 14.8, an increase of 22%, or 2.7 albacore per 1000 hooks. Monohull catch rates of albacore have been relatively stable, ranging from 12 to 18 fish between 2003 and 2012.

Calculation: These values are sums of the Longline Logbook albacore catch (number of fish kept + released) from the longline logs for the two types of longline vessels in Samoa, alias and mono-hulls, divided by the total number of hooks set by each type of vessel. The 2006 mono-hull value is the value for all vessels for confidentiality reasons.

American Samoa Longline Albacore CPUE (fish per 1000 hooks)

Year	Alias	Monohulls

TOTAL PELAGICS	**27.5**	**26.0**	**20.3**	**21.5**	**25.2**	**20.0**	**23.7**

Interpretation: The catch rate by all longline vessels from the past five years have generally been the same, ranging from 17 to 22 fishes for tuna species. The catch rate for tunas in 2012 was 21, an increase of 21%. Albacore tuna was the targeted species with a 14.8 catch rate. The non-tuna PMUS species catch are about constant in the previous five years at 2.0 to 2.5 fish.

Calculation: These values are sums of the Longline Logbook catch (number of fish kept + released) from the longline logs for the two types of longline vessels in Samoa, alias and monohulls, divided by the total number of hooks set by each type of vessel. All species of sharks entered in the Longline Logs are combined in the All Sharks species category. Rays and sunfish are included in the Misc Pelagic Fish category.

Figure 24. Albacore average weight per fish

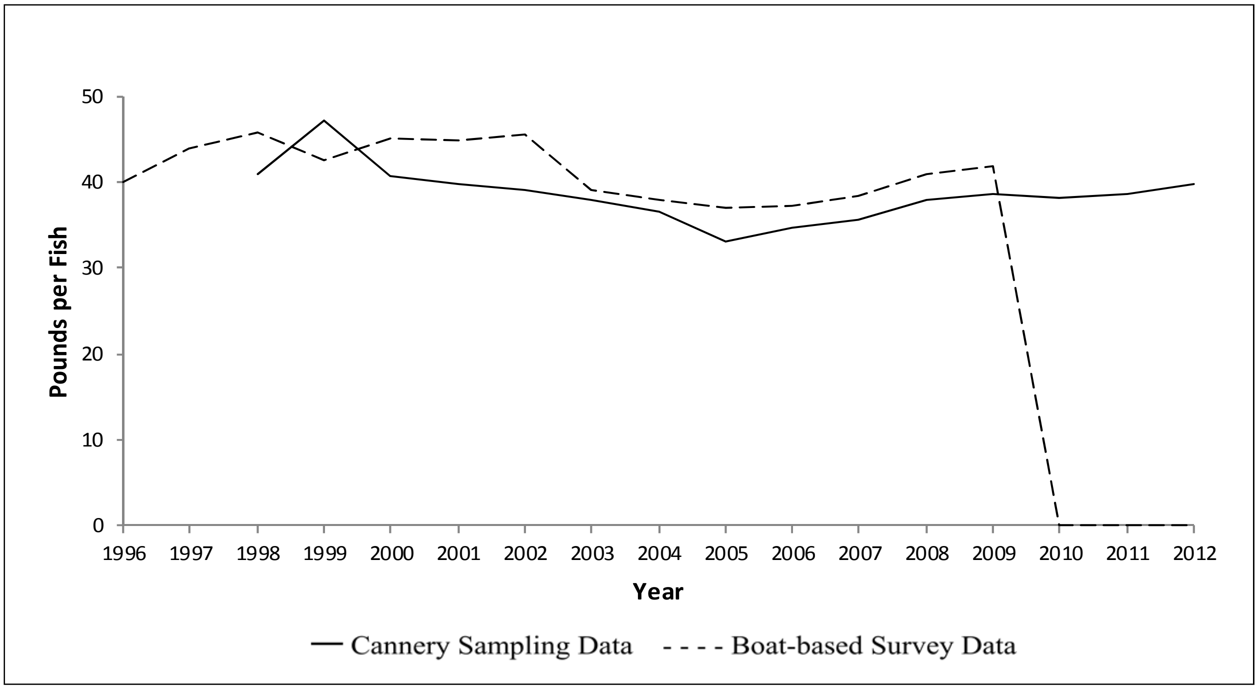

Figure 25. Average weight per fish for other tuna and cannery species (cannery-sampled)

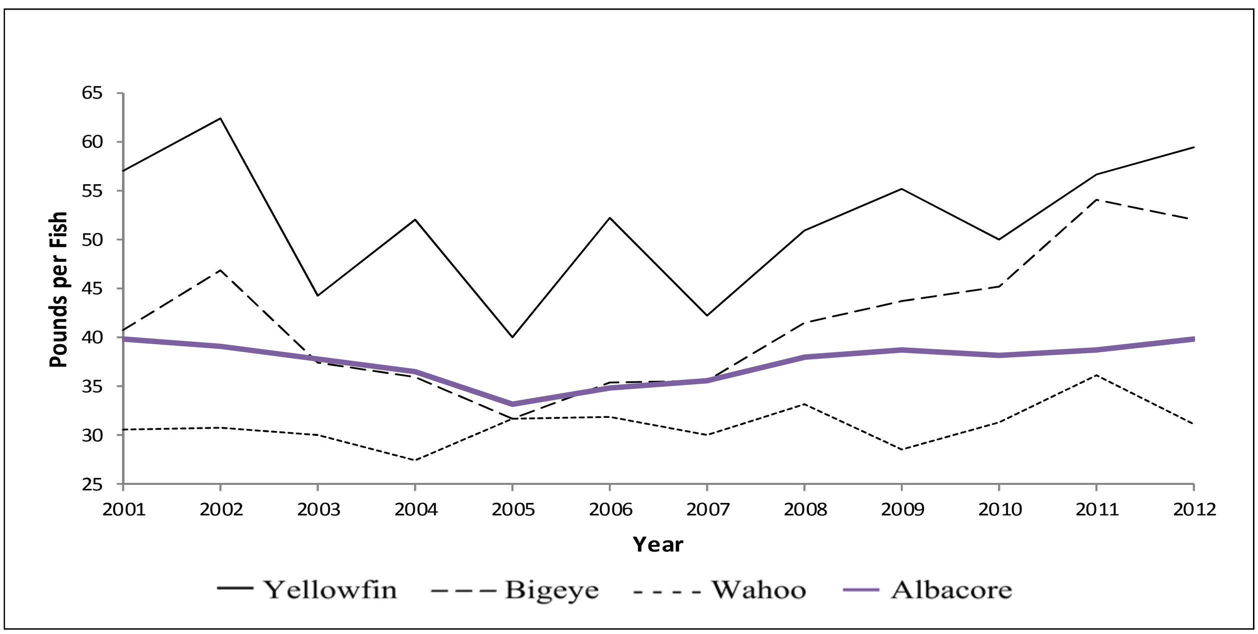

Interpretation: The cannery data represents the portion of the catch unloaded by larger vessels fishing farther away from Tutuila. The creel survey represents fish caught by alias near Tutuila. In 1999 longline boats began landing catches gilled and gutted to obtain higher prices at the canneries. This new method could have an impact on size variation for the longline fishery.

For the cannery sampled average weight per fish, about half of the weights increased and half decreased. Albacore average weight-per-fish increased slightly by 1 pound in 2012. In 2012, skipjack increased by 2.8 lbs, a 27% increase, and yellowfin increased by 2.7 lbs, representing a 5% increase. Bigeye decreased by 2 lbs and wahoo decreased by roughly 5 lbs.

Calculation: The Creel Survey Annual Average Pounds/Fish for each species was calculated from the creel survey interviews by dividing the total pounds of each species sampled during the year by the number of fish of sampled during the year. If the fish were sampled as other than whole (i.e. Gilled and Gutted) the sampled weight is divided by the appropriate factor (less than 1) to get the whole weight. All weights were measured directly before 2000, but after that most weights were calculated from length measurements. Since these fish are caught by alias operating close to Tutuila this represents fish sizes close to shore.

The Cannery Sampled Annual Average Pounds/Fish for each species was calculated from the length measurements made at the canneries when the fish are unloaded there. The weight of each sampled fish is calculated from the length measurements. These weights are summed over the year for each species and are then divided by the number of fish of that species sampled during the year. Since these fish are caught by larger boats operating away from Tutuila these catches represent fish sizes further out to sea from Tutuila.

Table 29. Cannery sampled average weight per fish in pounds (1998-2002)

Species	1998	1999	2000	2001	2002
Skipjack				16.8	11.3

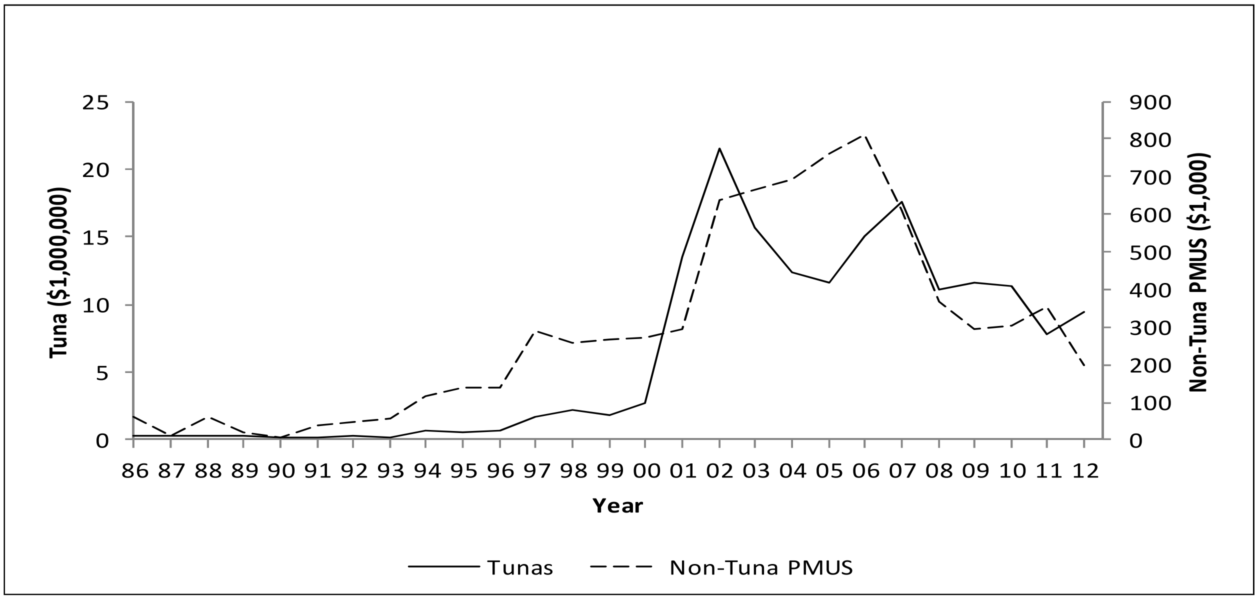
Figure 26. American Samoa annual inflation-adjusted revenue in 2012 dollars for tuna and non-tuna PMUS



Interpretation: Inflation-adjusted revenues for tunas increased in 2012, but decreased for non-tuna PMUS. Adjusted revenue for tunas increased by 23%, recovering from a slump in 2011 – the lowest adjusted revenue for tuna since 2000. Non-tuna adjusted revenues decreased by 44% from 2011. The adjusted revenue for tuna species peaked in 2002 at $21.5 million and peaked for non-tuna at $809,000 in 2006.

Calculation: The unadjusted revenues for Tunas and Other PPMUS were calculated by summing the values for the species in these categories as defined by Table 4. The unadjusted revenue for All Pelagics is the sum of the value for the Tuna, Other PPMUS and Miscellaneous categories as defined by Table 4.

The unadjusted revenues from commercial landings for the pelagic species subgroups above were adjusted for inflation by multiplying a given year's revenue by the 2000 consumer price index (CPI) divided by the CPI for that year.

Table 32. American Samoa commercial pelagic fishing revenues in unadjusted and inflation-adjusted dollars 1986-2012 including consumer price index (CPI)

		Revenue ($)			
		Tunas		Non-Tuna PMUS	
Year	CPI	Unadjusted	Adjusted	Unadjusted	Adjusted

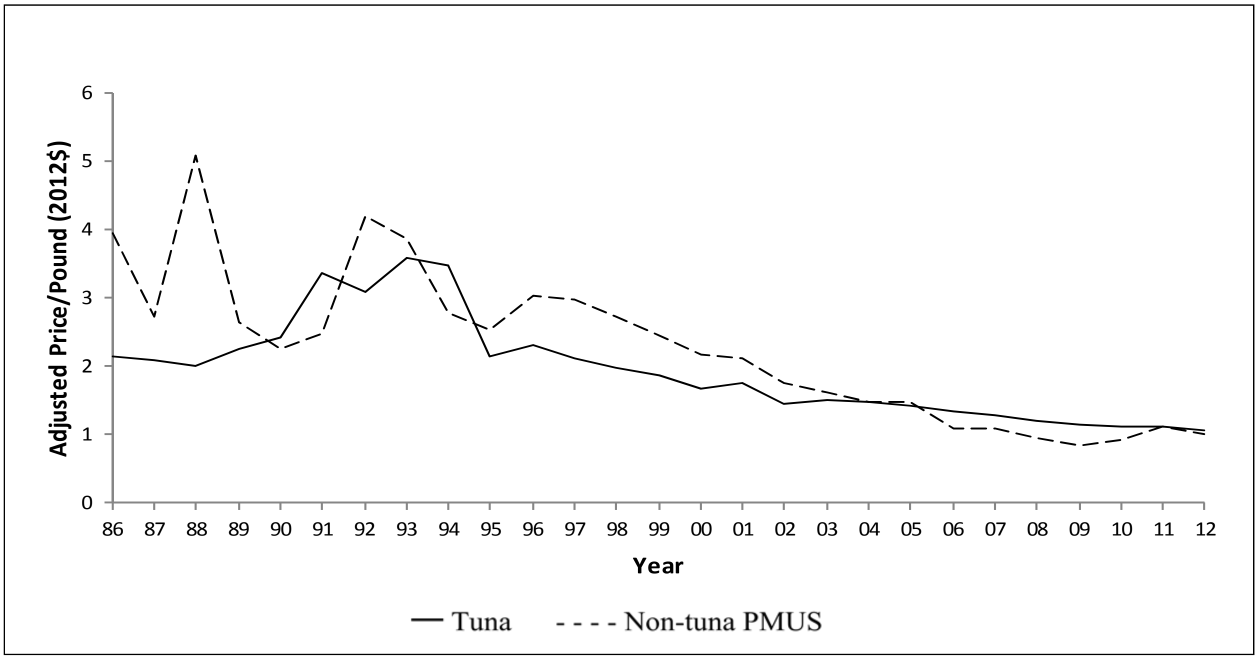
Figure 27. American Samoa average inflation-adjusted price per pound of tunas and non-tuna PMUS



Interpretation: The average inflation-adjusted price-per-pound for tunas decreased in 2012 by $0.04 (4%) from 2011 and decreased by $0.13 (12%) for non-tuna PMUS. Tuna price-per-pound peaked at $3.57 in 1993; the non-tuna PMUS average peaked in 1988 at $5.07. The 2012 inflation-adjusted price-per-pound for tuna PMUS is currently at its lowest level since 1986 at $1.07, while non-tuna PMUS was at its lowest price per pound in 2009 at $0.83.

Calculation: The unadjusted price/pound for Tunas and Non-Tuna PMUS were calculated by dividing the sum of the values for the species in these categories as defined by Table 4 by the sum of their commercial landings or pounds.

The unadjusted price/pound values for the pelagic species subgroups above were adjusted for inflation by multiplying the given year's price/pound by the 2006 consumer price index (CPI) divided by the CPI for that year.

Table 33. American Samoa average price per pound of tuna PMUS and non-tuna PMUS in unadjusted and inflation-adjusted dollars 1986-2012

	Average Price/Pound ($)

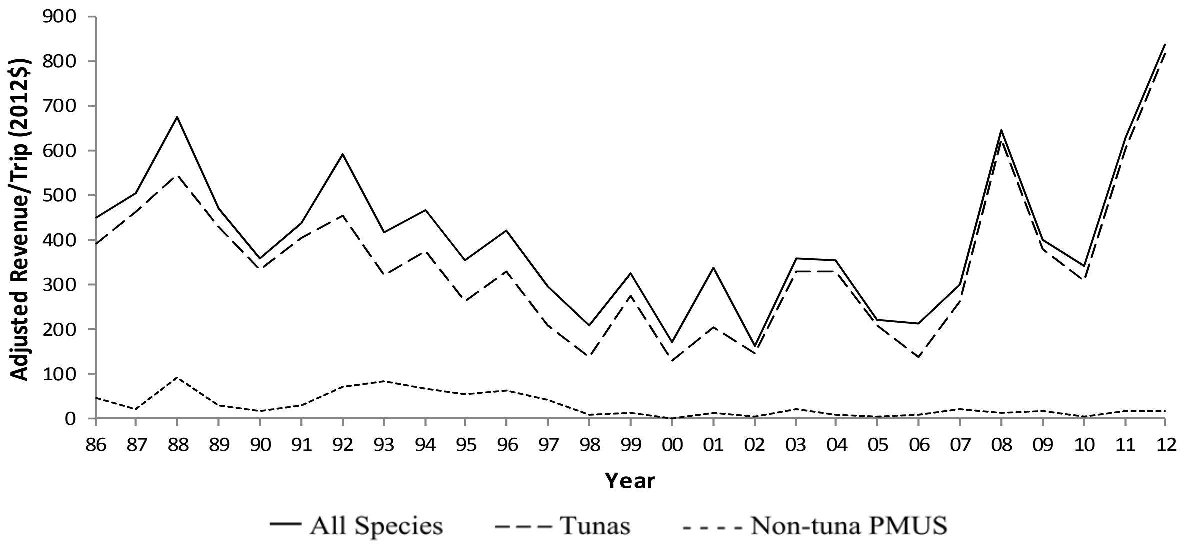
Figure 28. American Samoa average inflation-adjusted revenue per trolling trip landing pelagic species



Interpretation: Adjusted revenues per trolling trip for non-tunas increased by $1.20 in 2012 from 2011, an 8% increase. The 2012 average adjusted revenue-per-troll-trip for tunas increased to $816, a 349% increase over 2011. Skipjack and yellowfin are the primary tuna landings by trollers. The adjusted revenue-per-troll-trip for all species increased by $205, or 32.5%. The 2012 average revenue per trolling trip for tunas is the highest since recordings started in 1986.

Calculation: The purely trolling interviews in the offshore creel survey system landing any of the species listed in Table 3 and selling part or all of their catch are first counted for the given year to get the number of trips. The unadjusted revenue/trip for Tunas and Non-Tuna PMUS is calculated by first summing the value of the species in these pelagic subgroups caught and sold by purely trolling methods and then dividing this by the number of pure trolling trips. The unadjusted revenue/trip for all species is the sum of the value of all species, in Table 3 or not, caught by the purely trolling trips that sold all or part of their catch divided by the number of such trips. The unadjusted revenue/trip values for the pelagic species subgroups above and for all species were adjusted for inflation by multiplying the given year's revenue/trip by the 2003 consumer price index (CPI) divided by the CPI for that year.

Table 34. American Samoa commercial pelagic revenues in unadjusted and inflation-adjusted dollars per trip 1986-2012

	All Species		Tunas		Non-Tuna PMUS

B. Commonwealth of the Northern Mariana Islands

Introduction

The Northern Mariana Islands pelagic fishery occurs primarily from the island of Farallon de Medinilla south to the island of Rota. The fishery is characterized using data from the Commercial Receipt Invoice Database and the Boat-based Creel Survey. The commercial purchase collection system is dependent upon first-level purchasers of local fresh fish to accurately record all fish purchases by species categories on specially designed invoices. Staff from the Department of Lands and Natural Resources, Division of Fish and Wildlife (DFW) routinely distributes and collects invoice books from participating local fish purchasers on Saipan. This program is a voluntary program that includes purchasers at some fish markets, stores, restaurants, hotels and roadside vendors ("fish-mobiles").

The Commercial Purchase Database Collection System and the Boat-based Creel Survey is currently documenting landings only on the island of Saipan. The establishment of a data collection system for the islands of Tinian and Rota are in the process, however funding is an issue. It is believed that the commercial purchase database landings include around 90% of all commercial landings on Saipan. There is also a subsistence fishery on Saipan were profits are made by selling a small portion of catch to cover fishing expenses. Some fishermen sell their catch going “door to door,” which results in around 30% unreported commercial landings.

Although the Saipan Commercial Purchase Database Collection System has been in operation since the mid-1970s, only data collected since 1983 are considered accurate enough to be used.

The boat-based creel survey was re-implemented in April 2000 and is still ongoing. Data from this survey is used in this report and analyzes fishing activity only on the island of Saipan. Currently no boat-based creel survey programs are being conducted on the islands of Tinian and Rota.

Summary

Trolling is the primary fishing method utilized in the pelagic fishery. The pelagic fishing fleet, other than charter boats, consists primarily of vessels less than 24 ft in length, which usually have a limited 20-mile travel radius from Saipan.

Charter vessel landings from the Creel Survey are used in this report. Recorded Charter boat landings make up less than 2% of the total pelagics landings on Saipan.

The total pelagics landed in 2012 increased 33%. The primary target and most marketable species for the pelagic fleet are skipjack tuna. In 2012, skipjack tuna landings comprised over 60% of the entire pelagic landings. Schools of skipjack tuna have historically been common in near shore waters, providing an opportunity to catch numerous fish with a minimum of travel time and fuel costs. Skipjack is readily consumed by the local populace and restaurants, primarily as sashimi.

Yellowfin tuna and mahimahi are also easily marketable species but are seasonal. During their seasonal runs, these fish are usually found close to shore and provide easy targets for the local fishermen.

In late 2007, Crystal Seas became the first established longline fishing company in the CNMI to begin its operation out of the island of Rota. However, by 2009 Crystal Seas became Pacific Seafoods and relocated its operation to Saipan. In 2011, four licensed longline fishing vessels were stationed in the CNMI. Federal log book data are being collected and submitted to NMFS. This report did not include any data or landings from longline vessels.

Plan Team Recommendations

There were no recommendations made for 2012.

Table 35. CNMI Creel Survey 2012 pelagic species composition

Species	Total Landings (Lbs)	Non-Charter	Charter
Skipjack Tuna	288,642	287,482	1,160
Yellowfin Tuna	73,707	73,565	142
Kawakawa	24,680	24,580	100
Tuna PMUS	**387,029**	**385,627**	**1,402**
Mahimahi	39,236	38,015	1,221
Wahoo	18,456	16,301	2,156
Blue Marlin	9,751	9,751	0
Sailfish	0	0	0
Shortbill Spearfish	0	0	0
Non-tuna PMUS	**67,443**	**64,067**	**3,376**
Dogtooth Tuna	2,087	2,087	0
Rainbow Runner	525	525	0
Barracudas	144	0	144
Yellowtail Barracuda	0	0	0
Non-PMUS Pelagics	**2,756**	**2,612**	**144**
Total Pelagics	**457,228**	**452,306**	**4,922**

Interpretation: Skipjack tuna continued to dominate the pelagic landings, comprising around 63% of the total pelagic catch. Skipjack tunas are easily caught in near shore waters throughout the year. Mahimahi is seasonal with peak catch usually from February through April. Yellowfin season usually runs from April to September. The overall pelagic catch increased 33% in 2012.

Source and Calculations: Data are from the Division of Fish and Wildlife (DFW) boat-based creel survey. A 365-day (366 days during leap years) annual expansion is run for each calendar year of survey data to produce catch and effort estimates for the pelagic fishery to avoid over-estimating seasonal pelagic species. Percent species composition is calculated by weight for the sampled catch for each method to produce catch estimates for each species for the expanded period. The annual catch for all pelagic species and the PMUS separately are summed across all methods to obtain the numbers plotted above.

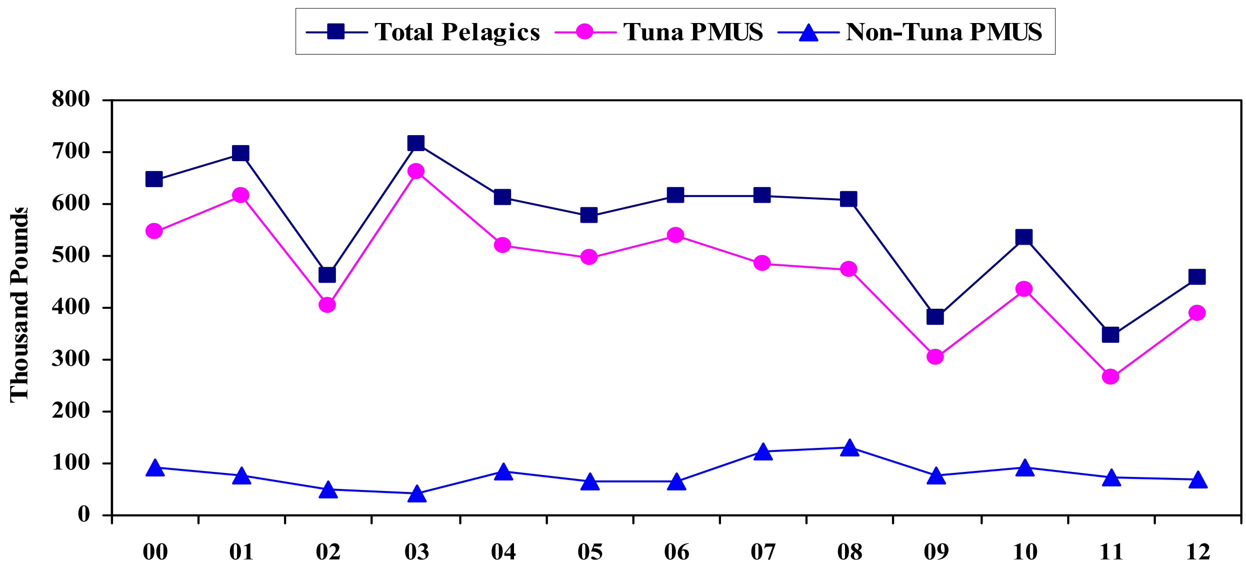
Table 36. CNMI 2012 estimated commercial pelagic landings, revenues and price (from Commercial Receipt invoices)

Species	Landing (Lbs)	Value ($)	Avg. Price ($/Lb)
Skipjack Tuna	99,187	192,810	1.94
Yellowfin Tuna	19,392	41,494	2.14
Saba (kawakawa)	774	1,599	2.07
Tunas (misc.)	6,004	9,996	1.66
Tuna PMUS	**125,356**	**245,899**	**1.96**
Mahimahi	18,712	40,704	2.18
Wahoo	8,677	19,363	2.23
Blue Marlin	2,010	4,385	2.18
Sailfish	25	49	2.00
Sickle Pomfret (w/woman)	493	1,040	2.11
Non-tuna PMUS	**29,917**	**65,542**	**2.19**
Dogtooth Tuna	5,072	12,210	2.41
Rainbow Runner	368	803	2.18
Non-PMUS Pelagics	**5,440**	**13,013**	**2.39**
Total Pelagics	**160,714**	**324,454**	**2.02**

Interpretation: In 2012, Skipjack tuna dominated the pelagic landings, comprising around 62% of the (commercially receipted) industry's pelagic catch. In 2012, yellowfin tuna and mahimahi ranked second and third in total landings. Skipjack tunas are easily caught in near shore waters throughout the year. Mahimahi is seasonal with catch peak usually from February through April. Yellowfin season usually runs from April to September. The 2012 total pelagic recorded catch sold increased 33% over 2011.

The highest average price of identified pelagic species was $2.41/lb for dogtooth tuna. The lowest priced species was skipjack tuna, which sold at an average price of $1.94/lb and is the main target in the CNMI pelagic fishery.

Figure 29. Annual CNMI boat-based creel estimated total landings for all pelagics, tuna PMUS, and non-tuna PMUS



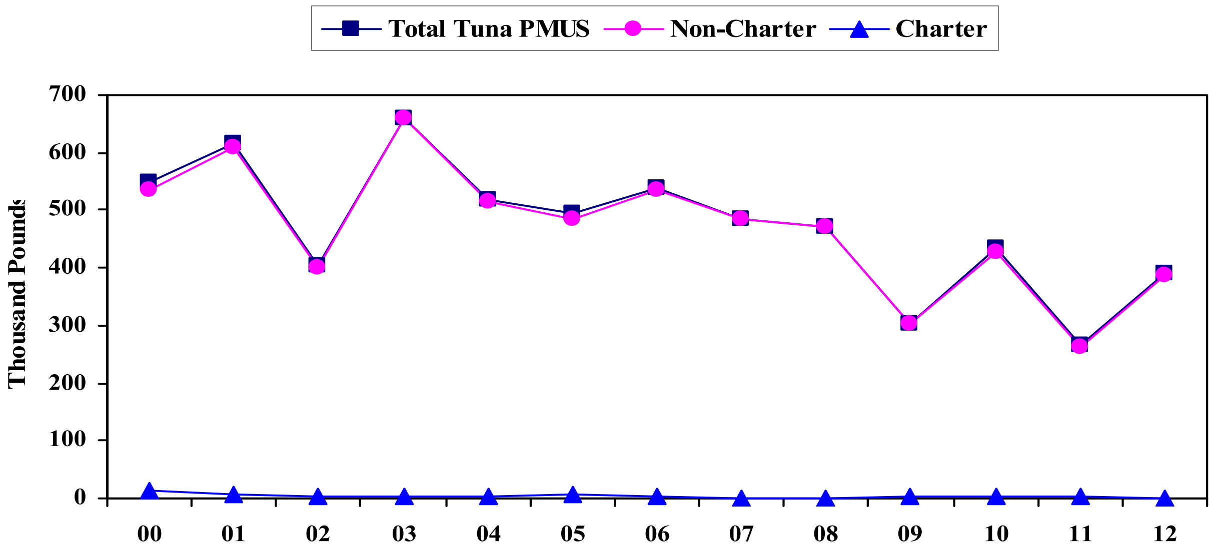
Interpretation: Creel survey landings declined in 2002, possibly due to several typhoons hitting the Mariana Islands. Since then, landings of pelagic species have been relatively stable until 2009 when landings of tuna PMUS decreased 42% because fewer fishing trips were taken and fishermen took shorter trips. The decrease in 2011 tuna PMUS landings of by 35% from 2010 was partly due to many days of unfavorable weather conditions. In 2012, tuna PMUS landings increased 46% over the 2011 landings with fishermen reporting better catch rates and favorable fishing conditions.

Annual Boat-based Creel Estimated Landings (lbs)

Year	All Pelagics	Tuna PMUS	Non-Tuna PMUS
2000	644,324	547,441	91,536
2001	695,382	614,330	78,164
2002	461,332	403,062	51,064
2003	714,407	660,805	42,584
2004	613,002	518,362	82,773
2005	576,312	494,493	64,661
2005	614,002	539,455	66,757
2007	615,267	486,000	124,996
2008	608,809	472,703	132,312
2009	381,380	303,522	76,308
2010	535,291	432,829	90,694
2011	344,999	265,857	71,681
2012	457,227	389,116	67,442
Average	558,636	471,383	80,075
Standard Deviation	110,902	108,497	24,664

Source and Calculations: Data are from the Division of Fish and Wildlife (DFW) boat-based creel survey. A 365-day (366 days during leap years) annual expansion is run for each calendar year of survey data to produce catch and effort estimates for the pelagic fishery to avoid over-estimating seasonal pelagic species. Percent species composition is calculated by weight for the sampled catch for each method to produce catch estimates for each species for the expanded period. The annual catch for total of pelagic species, Tuna PMUS and Non-Tuna PMUS separately are summed across all methods to obtain the numbers plotted above.

Figure 30. Annual CNMI boat-based creel estimated tuna landings for all, non-charter, and charter pelagics for 2000-2012



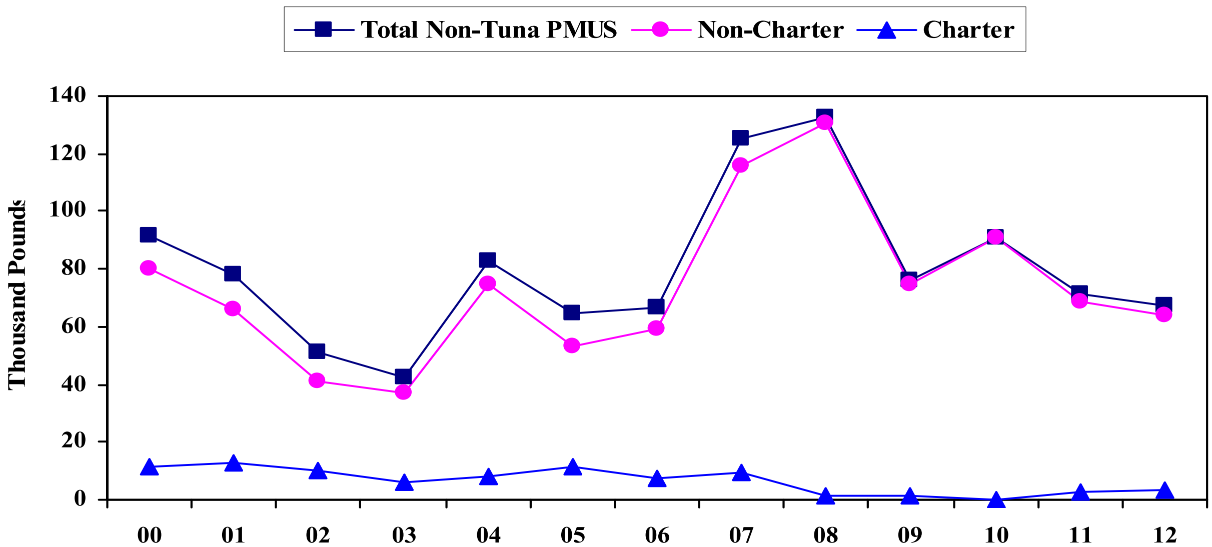
Interpretation: Total landings over the time series indicate that 98% of all tuna PMUS are landed by non-charter vessels. 2011 non-charter landings decreased 38% over 2010, but increased in 2012 by 48%. 2010 charter landings increased significantly by 51% over 2009. 2011 charter landings were similar to 2010, while charter landings decreased by 65% in 2012.

Boat-based Creel Estimated Tuna Landings (lbs)

Year	Total Tunas	Non-charter	Charter
2000	547,441	534,708	12,733
2001	614,330	608,705	5,625
2002	403,062	400,848	2,214
2003	660,805	658,123	2,862
2004	518,362	515,420	2,942
2005	494,493	486,196	8,297
2006	539,455	535,838	3,617
2007	486,000	485,025	975
2008	472,703	471,294	1,408
2009	303,522	301,207	2,315
2010	432,829	428,786	4,043
2011	265,857	263,724	4,002
2012	389,116	387,713	1,403
Average	471,383	467,363	4,020
Standard Deviation	108,497	107,661	3,150

Source and Calculations: Data are from the Division of Fish and Wildlife (DFW) boat-based creel survey. A 365-day (366 days during leap years) annual expansion is run for each calendar year of survey data to produce catch and effort estimates for the pelagic fishery to avoid over-estimating seasonal pelagic species. Percent species composition is calculated by weight for the sampled catch for each method to produce catch estimates for each species for the expanded period. The annual catch for total tuna PMUS, charter and non-charter separately are summed across all methods to obtain the numbers plotted above.

Figure 31. Annual CNMI boat-based creel estimated non-tuna PMUS landings for all, non-charter, and charter pelagics for 2000-2012

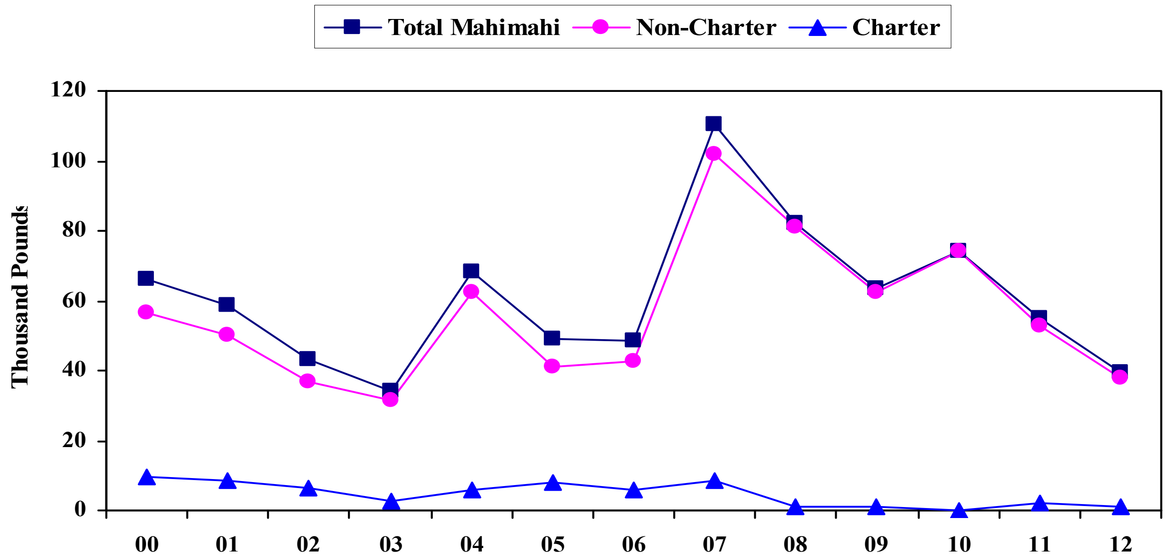


Interpretation: The 2010 total non-tuna PMUS increased slightly over 2009 figures by 16%, mostly due to the increased mahimahi and wahoo landings. 2011 non-tuna landings decreased by 19%, and decreased another 6% in 2012. The non-charter 2011 landings decreased 23% over previous year and decreased further in 2012.

Source and Calculations: Data are from the Division of Fish and Wildlife (DFW) boat-based creel survey. A 365-day (366 days during leap years) annual expansion is run for each calendar year of survey data to produce catch and effort estimates for the pelagic fishery to avoid over-estimating seasonal pelagic species. Percent species composition is calculated by weight for the sampled catch for each method to produce catch estimates for each species for the expanded period. The annual catch for Total Non-Tuna PMUS, Charter and Non-Charter separately are summed across all methods to obtain the numbers plotted above.

Non-tuna PMUS Landings (lbs)			
Year	Total Non-tuna PMUS	Non-charter	Charter
2000	91,536	80,029	11,507
2001	78,164	65,692	12,472
2002	51,064	41,246	9,819
2003	42,584	36,827	5,758
2004	82,773	74,416	8,357
2005	64,661	52,898	11,762
2006	66,757	59,223	7,533
2007	124,996	115,861	9,135
2008	132,312	130,854	1,458
2009	76,308	74,929	1,379
2010	90,694	90,694	0
2011	71,681	69,439	4,050
2012	67,442	64,066	3,376
Average	80,075	73,502	6,573
Standard Deviation	24,664	25,736	4,188

Figure 32. Annual CNMI boat-based creel estimated mahimahi landings



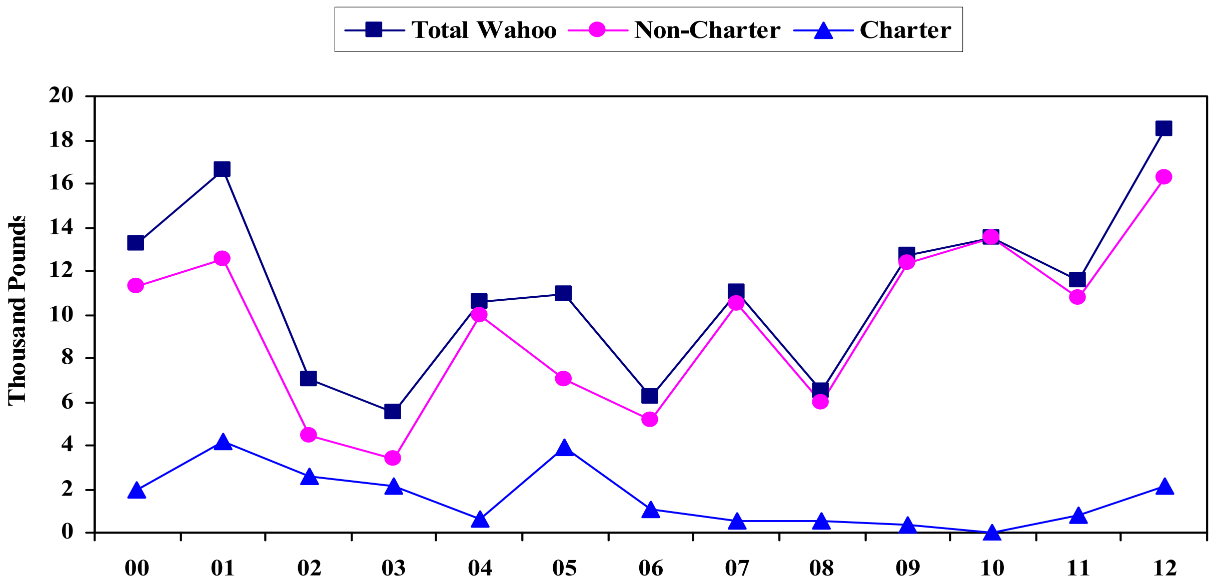
Interpretation: Mahimahi landings have fluctuated yearly, usually in a two year cycle. The bulk of mahimahi landings are from non-charter vessels. Although mahimahi is a favorite target by charter boats, the decreasing number of tourists arriving into Saipan has deeply impacted the charter fishing industry.

2010 landings increased by 16% over 2009 landings, however landings declined in 2011 (24%) and again in 2012 (29%). Non-charter landings decreased by 28% and charter mahi landings decreased significantly by 42% in 2012.

Mahimahi Landings (lbs)			
Year	Total Mahimahi	Non-Charter	Charter
2000	66,230	56,719	9,512
2001	58,548	50,219	8,328
2002	43,149	36,774	6,375
2003	34,128	31,338	2,790
2004	68,302	62,433	5,869
2005	48,960	41,122	7,839
2006	48,666	42,729	5,937
2007	110,351	101,792	8,559
2008	81,912	81,025	887
2009	63,559	62,568	991
2010	73,965	73,965	0
2011	54,935	52,846	2,089
2012	39,235	38,015	1,221
Average	60,918	56,273	4,646
Standard Deviation	19,577	19,359	3,278

Source and Calculations: Data are from the Division of Fish and Wildlife (DFW) boat-based creel survey. A 365-day (366 days during leap years) annual expansion is run for each calendar year of survey data to produce catch and effort estimates for the pelagic fishery to avoid over-estimating seasonal pelagic species. Percent species composition is calculated by weight for the sampled catch for each method to produce catch estimates for each species for the expanded period. The annual catch for Total Mahimahi, Charter and Non-Charter are separately summed across all methods to obtain the numbers plotted above.

Figure 33. Annual CNMI boat-based creel estimated wahoo landings

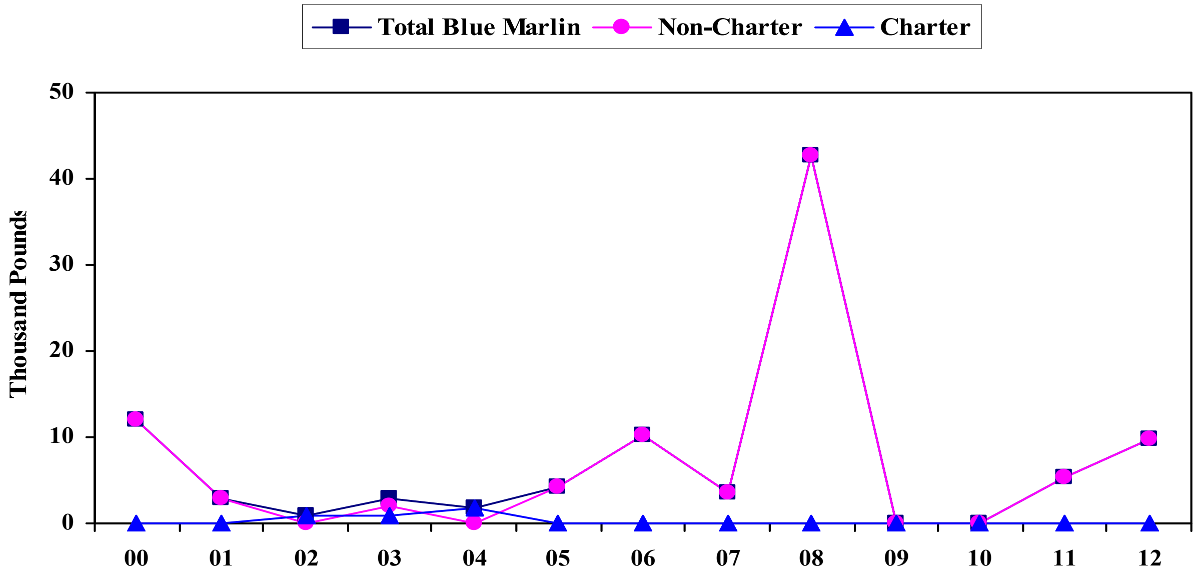


Interpretation: Wahoo landings have fluctuated yearly with majority of landings being made by non-charter vessels. Total wahoo landings increased in 2010 by 6% over 2009 landings. There were no wahoo landings recorded during creel survey sample days of charter boats in 2010. 2011 total wahoo landing decreased 12% over 2010 with non-charter landings decreasing 20% over the previous year. Total wahoo landings increased significantly by 60% in 2012 with non-charter wahoo landings increasing 52% and charter landings increasing significantly by 169%. Fishermen reported a good year for landing wahoo in 2012.

Wahoo Landings (lbs)			
Year	Total Wahoo	Non-Charter	Charter
2000	13,282	11,287	1,996
2001	16,653	12,509	4,144
2002	7,060	4,471	2,589
2003	5,528	3,417	2,110
2004	10,537	9,924	613
2005	10,956	7,033	3,924
2006	6,225	5,141	1,085
2007	11,023	10,447	576
2008	6,525	5,954	571
2009	12,750	12,362	388
2010	13,494	13,494	0
2011	11,516	10,714	802
2012	18,456	16,301	2,155
Average	11,077	9,466	1,612
Standard Deviation	3,830	3,774	1,289

Source and Calculations: Data are from the Division of Fish and Wildlife (DFW) boat-based creel survey. A 365-day (366 days during leap years) annual expansion is run for each calendar year of survey data to produce catch and effort estimates for the pelagic fishery to avoid over-estimating seasonal pelagic species. Percent species composition is calculated by weight for the sampled catch for each method to produce catch estimates for each species for the expanded period. The annual catch for Total Wahoo landings, Charter and Non-Charter separately are summed across all methods to obtain the numbers plotted above.

Figure 34. Annual CNMI boat-based creel estimated blue marlin landings



Interpretation: Blue marlin is rarely targeted by non-charter vessels. Charter vessels would prefer to land blue marlin but seldom do due to the short fishing time (average is 4 hours) that tourists charter their vessels. Non-charter fishermen find it difficult to find a market for blue marlin landings. Although the majority of the fishing is done by non-charter vessels, these vessels are usually smaller in size (15-18 feet in length), making it difficult to haul blue marlin. During 2009 and 2010 there was no blue marlin landings recorded during creel survey sample days, but in 2011, non-charter vessels landed over 5,000 pounds. In 2012, non-charter vessels recorded total blue marlin landings of nearly 10,000 pounds. No landings from charter vessels were recorded during creel survey samples in 2012.

Blue Marlin Landings (lbs)			
Year	Total Blue Marlin	Non-Charter	Charter
2000	12,024	12,024	0
2001	2,963	2,963	0

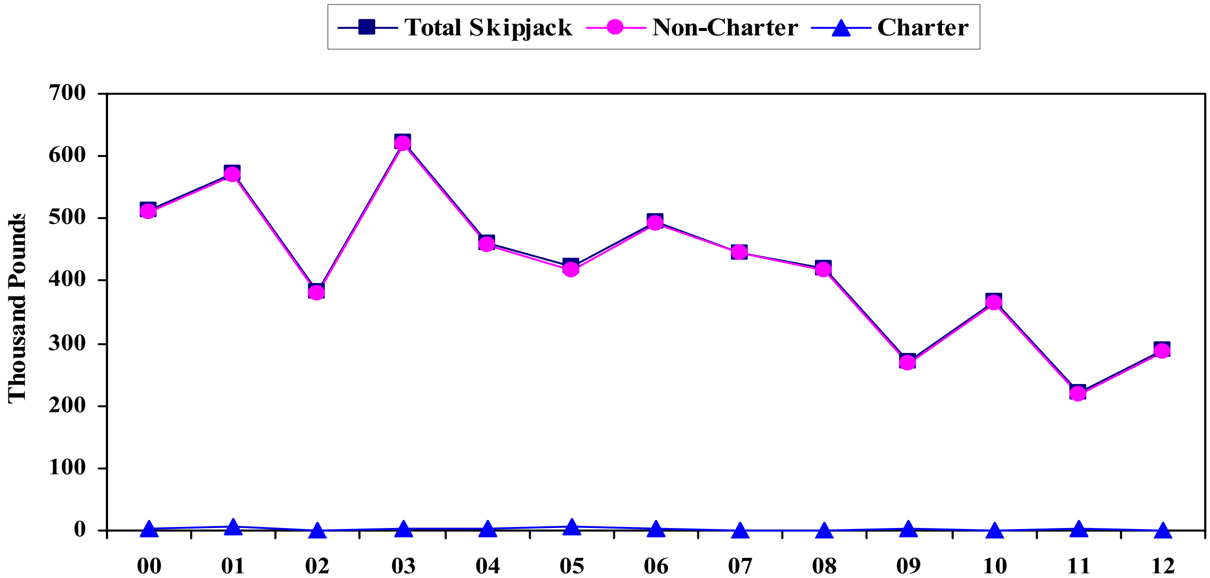
2012	9,751	9,751	0
Average	7,403	7,127	276
Standard Deviation	10,828	10,981	554

Source and Calculations: Data are from the Division of Fish and Wildlife (DFW) boat-based creel survey. A 365-day (366 days during leap years) annual expansion is run for each calendar year of survey data to produce catch and effort estimates for the pelagic fishery to avoid over-estimating seasonal pelagic species. Percent species composition is calculated by weight for the sampled catch for each method to produce catch estimates for each species for the expanded period. The annual catch for blue marlin, Charter and Non-Charter separately are summed across all methods to obtain the numbers plotted above.

Figure 35. Annual CNMI boat-based creel estimated skipjack tuna landings

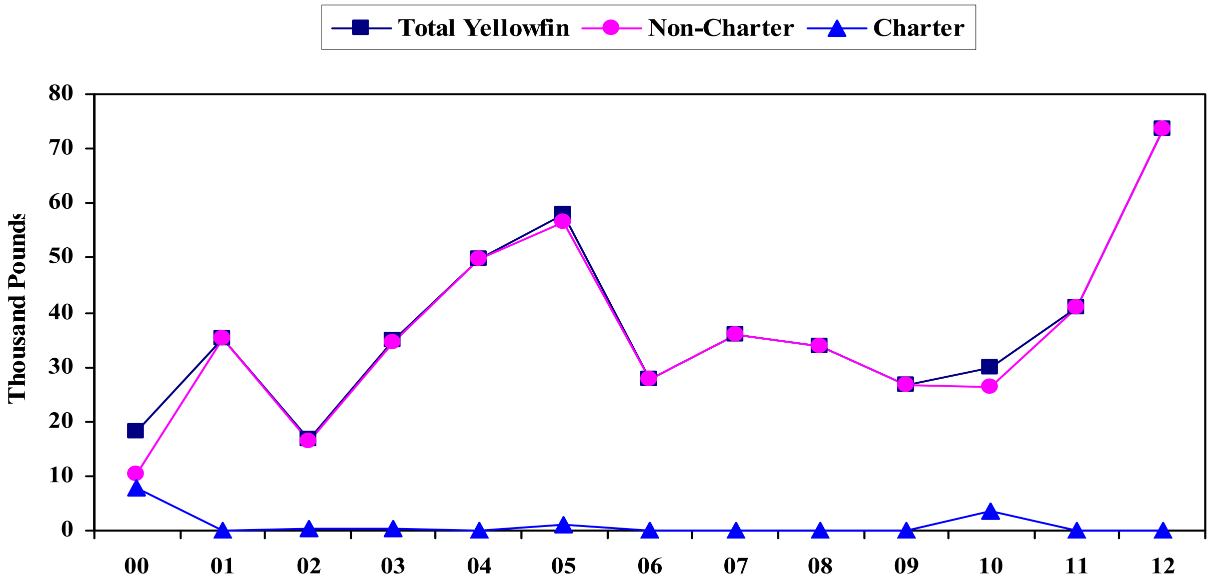


Interpretation: Skipjack tuna make up the majority of all pelagic landings. A drop in 2002 landings may be attributed to several typhoons that hit the Mariana Islands. Skipjack landings spiked in 2003, possibly due to increased fishing efforts. 2009 landings decreased 36% over 2008, which is a reflection of the Saipan economy and rising fuel prices. 2010 skipjack landings increased 37% over 2009, but decreased 39% in 2011. This decrease may be partially due to increasing fuel prices, the current economic situation in CNMI, and unfavorable sea conditions for fishing, which caused several long-time troll fishermen to leave the fishery. Total skipjack landings in 2012 increased 30% from 2011. Non-charter landings indicate an increase of 32% while charter landings indicate a significant decrease of 71%.

Skipjack Tuna Landings (lbs)			
Year	Total Skipjack	Non-Charter	Charter
2000	514,027	510,678	3,350
2001	573,996	569,041	4,955
2002	381,612	380,062	1,550
2003	621,204	619,130	2,073
2004	460,626	457,966	2,660
2005	424,597	418,340	6,258
2006	494,927	491,520	3,407
2007	444,493	443,600	893
2008	419,311	417,903	1,408
2009	270,439	268,484	1,955
2010	365,636	365,192	444
2011	221,575	217,633	3,943
2012	288,642	287,482	1,160
Average	**421,622**	**419,002**	**2,620**
Standard Deviation	**112,426**	**112,066**	**1,636**

Source and Calculations: Data are from the DFW boat-based creel survey. A 365-day (leap year = 366 days) annual expansion is run for each calendar year of survey data to produce catch and effort estimates for the pelagic fishery to avoid over-estimating seasonal pelagic species. Percent species composition is calculated by weight for the sampled catch for each method to produce catch estimates for each species for the expanded period. The annual catch for Skipjack Tuna, Charter and Non-Charter separately are summed across all methods to obtain the numbers plotted above.

Figure 36. Annual CNMI boat-based creel estimated yellowfin landings



Interpretation: In 2010, yellowfin tuna comprised only 6% of all total pelagic landings. Yellowfin tuna catches are usually smaller in size than other geographical areas; the average size of yellowfin tuna measured during creel survey on Saipan was 48.7 cm in length. Fishermen on Saipan recorded a good year for yellowfin tuna in 2011, with landings increasing over 2010 by 39%. There were no yellowfin tuna landings from charter vessels recorded in the boat-based creel survey in 2011. Total yellowfin landings increased in 2012 by 80%. 99.8% of the yellowfin landings in 2012 were from non-charter landings. Fishermen reported a longer season of yellowfin schools around Saipan.

Yellowfin Tuna Landings (lbs)			
Year	Total Yellowfin	Non-Charter	Charter
2000	18,123	10,195	7,928
2001	35,265	35,265	0

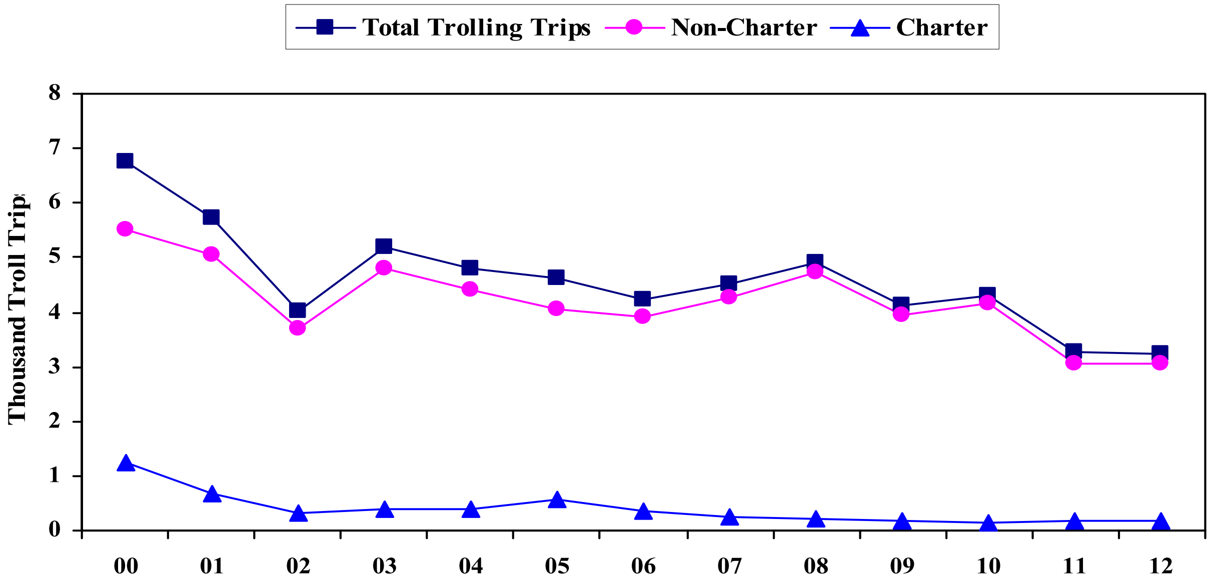
2012	77	134	127	7	126	119	7

Figure 37. CNMI boat-based creel estimated number of trolling trips

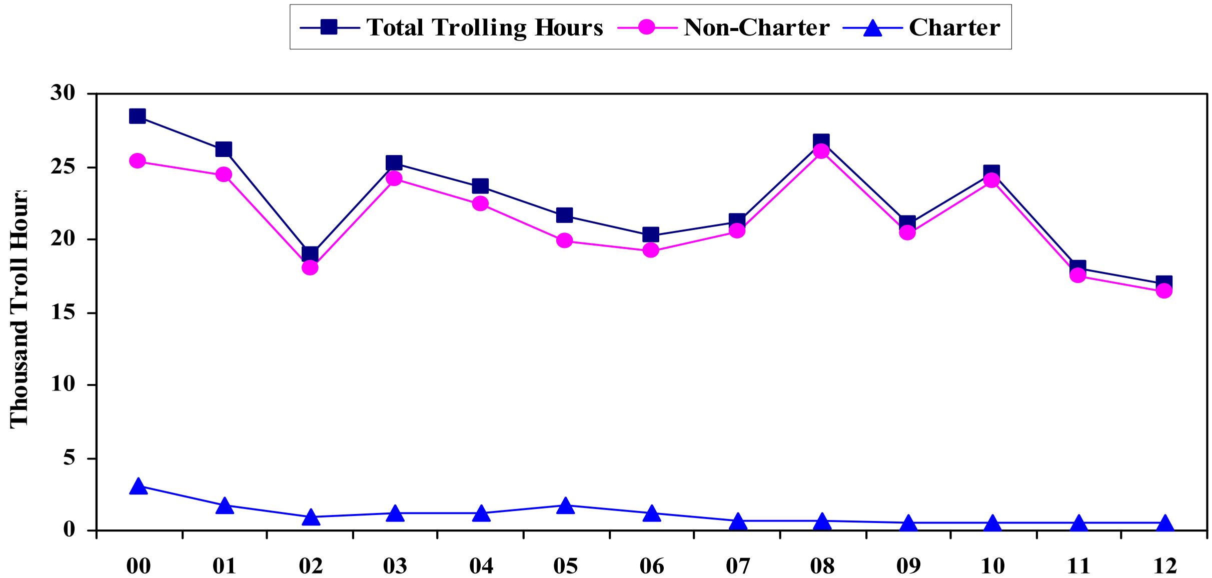


Interpretation: The total number of trolling trips has slightly decreased over the 12 years since the start of the boat-based creel survey, which is partly due to the down turn in economic activity in CNMI, rising fuel cost, and fishermen leaving the fishery. Despite this, 2010 total trips increased 5% over 2009 because non-charter boats trips increased 6% over 2009. Charter trips decreased 17% in 2010. In 2011, the number of total estimated trips decreased 22%; non-charter trips decreased 26% and, while charter trips increased by 19%, charter trips only represent 5.8% of the 2011 trips. The number of trolling trips in 2012 remained relatively the same as 2011, while charter trips declined slightly by 8%. The majority of trolling trips are from non-charter boats, which recorded 3,069 of the 3,242 total trips in 2012.

CNMI Estimated Number of Trips			
Year	Total Trips	Non-Charter	Charter
2000	6,755	5,528	1,227
2001	5,709	5,039	671
2002	4,001	3,683	318
2003	5,181	4,804	377
2004	4,810	4,412	398
2005	4,616	4,064	553
2006	4,235	3,896	340
2007	4,504	4,261	242
2008	4,921	4,717	204
2009	4,141	3,951	190
2010	4,312	4,154	158
2011	3,262	3,074	188
2012	3,242	3,069	173
Average	4,591	4,204	388
Standard Deviation	911	687	284

Source and Calculations: Data are from the Division of Fish and Wildlife (DFW) boat-based creel survey. The data expansion system is run on a calendar year's worth of survey data to produce catch and effort estimates for each fishing method surveyed. These plots are of the estimated number of trips for the trolling method as taken directly from creel survey expansion outputs.

Figure 38. CNMI boat-based creel estimated number of trolling hours

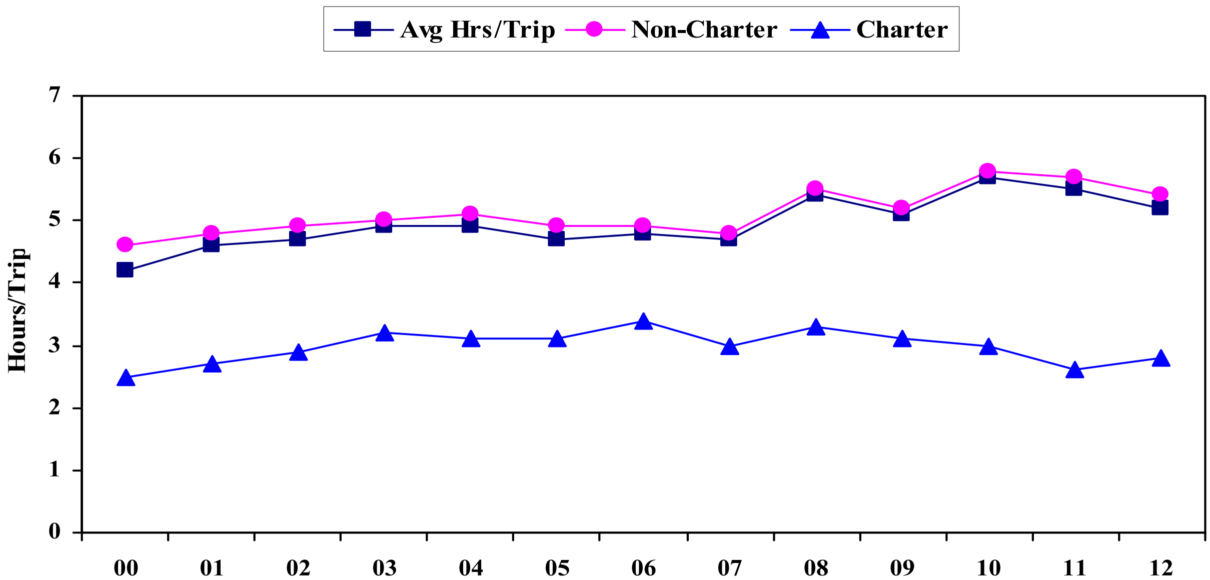


Interpretation: In 2011, total estimated trolling hours decreased 25% from 2010; trolling hours for non-charter boats decreased 27% from 2010, while charter trolling hours increased by 5%. In 2012, the total estimated trolling hours decreased by 6%; non-charter boat trolling hours decreased 6% and charter trolling hours decreased by 3%.

Source and Calculations: Data are from the Division of Fish and Wildlife (DFW) boat-based creel survey. The data expansion system is run on a calendar year's worth of survey data to produce catch and effort estimates for each fishing method surveyed. These plots are of the estimated boat hours spent fishing for the trolling method as taken directly from creel survey expansion outputs.

CNMI Estimated Trolling Hours			
Year	**Total Hours**	**Non-Charter**	**Charter**
2000	28,425	25,349	3,077
2001	26,166	24,370	1,796
2002	18,870	17,940	930
2003	25,266	24,078	1,188
2004	23,623	22,375	1,248
2005	21,619	19,915	1,705
2006	20,299	19,160	1,140
2007	21,232	20,499	733
2008	26,642	25,969	673
2009	21,027	20,443	584
2010	24,473	24,000	473
2011	17,973	17,475	498
2012	16,928	16,447	481
Average	22,503	21,386	1,117
Standard Deviation	3,426	3,051	709

Figure 39. CNMI boat-based creel estimated average troll trip length (hours/trip)

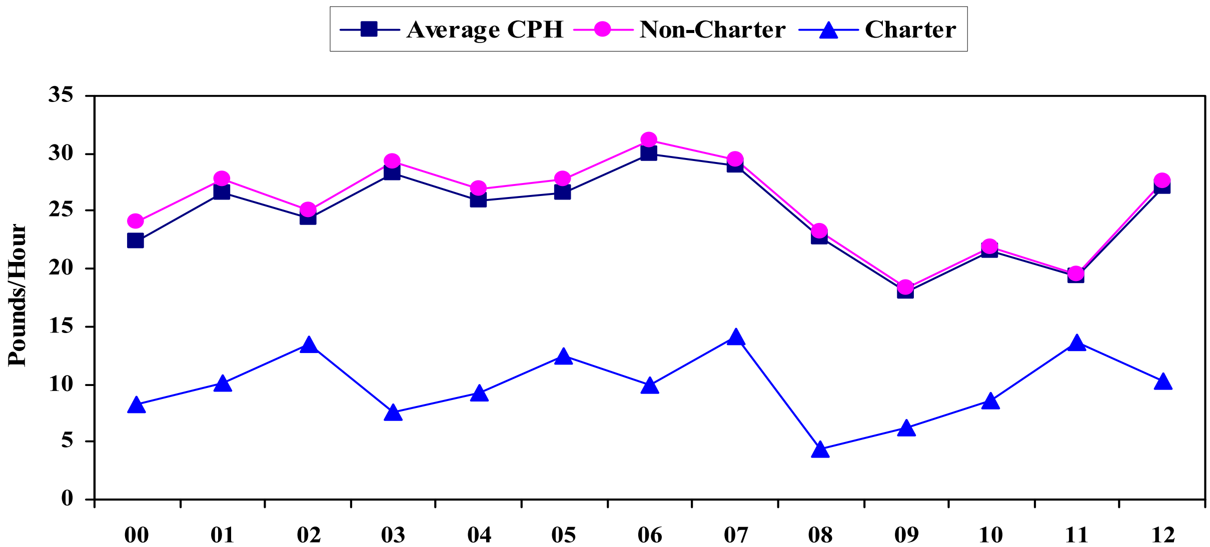


Estimated Troll Trip Length			
Year	Average Hours/Trip	Non-Charter	Charter
2000	4.2	4.6	2.5
2001	4.6	4.8	2.7
2002	4.7	4.9	2.9
2003	4.9	5.0	3.2
2004	4.9	5.1	3.1
2005	4.7	4.9	3.1
2006	4.8	4.9	3.4
2007	4.7	4.8	3.0
2008	5.4	5.5	3.3
2009	5.1	5.2	3.1
2010	5.7	5.8	3.0
2011	5.5	5.7	2.6
2012	5.2	5.4	2.8
Average	5.0	5.1	3.0
Standard Deviation	0.4	0.4	0.3

Interpretation: The overall average trolling hours/trips have increased over the 12 year time series. Total average trip length in 2010 increased 12% because non-charter boats fished longer hours, possibly due to remaining fishermen fishing longer to meet the demand in the market created when some fishermen left the industry. Total hours per trip taken in 2011 decreased by 4%; non-charter boats hours per trip decreased 2% and charter hours per trip decreased 10%. The 2011 decrease may be attributed to unfavorable sea conditions and rising fuel prices. The 2012 combined hours per trip data indicates a 5% decrease. In 2012, non-charter boat hours per trip decreased slightly by 5% due to better trolling catch rates. Charter boat hours per trip increased by 8% in 2012, partly due to lower catch rates being reported by the charter fleet and tourists requesting longer fishing trips. Favorable sea conditions also play a major role in hours/trips that non-charter and charter boats spend in the ocean.

Source and Calculations: Data are from the Division of Fish and Wildlife (DFW) boat-based creel survey. The data expansion system is run on a calendar year's worth of survey data to produce catch and effort estimates for each fishing method surveyed. These plots are of the estimated boat hours spent fishing and number of trips for the trolling method, as taken directly from creel survey, expansion system outputs.

Figure 40. CNMI boat-based creel trolling CPUE (pounds/hour) for all pelagic species

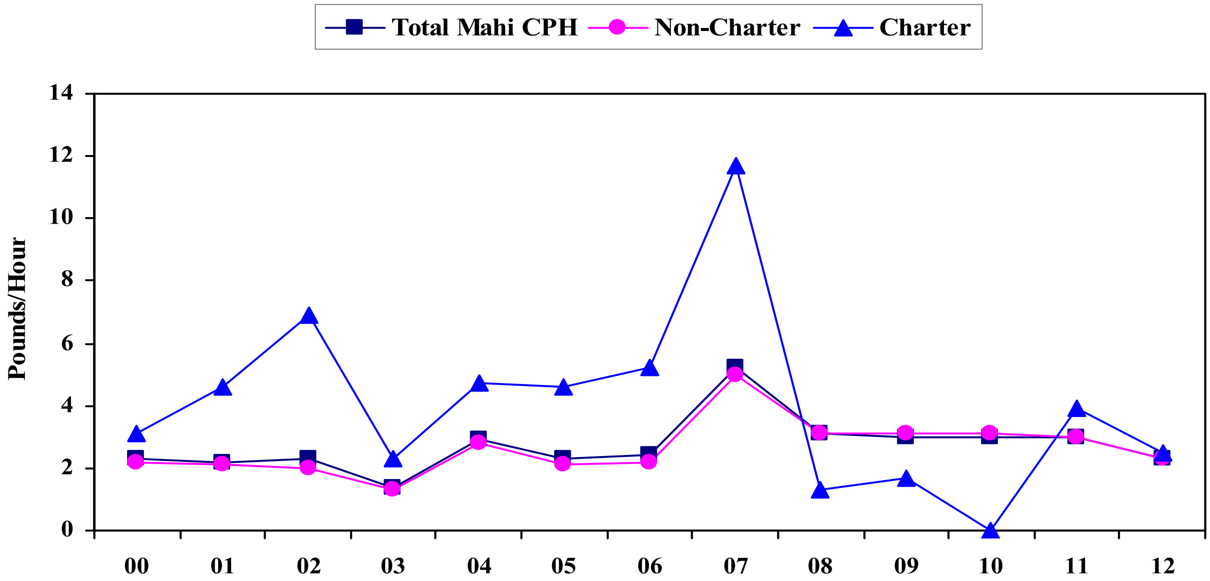


Interpretation: The trolling catch rates yearly fluctuations may be associated with weather patterns that affect sea conditions. 98% of total pelagic fish landed are from non-charter vessels, which are usually smaller boats, to target mainly skipjack. Smaller boats allow fishermen to save on fuel costs by using smaller boat engines. However, it also affects their ability to fish efficiently during rough weather days. 2010 pounds/hour for all pelagics increased 21% from 2009, decreased by 10% in 2011, but increased by 40% in 2012. Non-charter boats and charter vessels increased 20% and 89% respectively in 2010. The 2011 non-charter catch rates for all pelagics decreased by 10%, but increased by 42% in 2012. Charter boats increased consistently from 2008 through 2011, with a 55% increase from 2010 to 2011. However, charter boat catch rates declined by 26% in 2012.

CPUE (pounds/hour): All Pelagic Species			
Year	**Combined Average**	**Non-Charter**	**Charter**
2000	22.4	24.1	8.2
2001	26.6	27.8	10.1
2002	24.4	25.0	13.4
2003	28.3	29.3	7.5
2004	25.9	26.9	9.3
2005	26.6	27.8	12.4
2006	29.9	31.1	9.9
2007	29.0	29.5	14.2
2008	22.8	23.3	4.4
2009	18.0	18.3	6.3
2010	21.6	21.9	8.5
2011	19.3	19.5	13.7
2012	27.1	27.6	10.2
Average	24.8	25.5	9.9
Standard Deviation	3.6	3.8	2.9

Source and Calculations: Data are from the Division of Fish and Wildlife (DFW) boat-based creel survey. The data expansion system is run on a calendar year's worth of survey data to produce catch and effort estimates for each fishing method. This plot and table of catch per unit of effort (CPUE) are based on the total annual landings of all troll catch, divided by the total number of hours spent fishing.

Figure 41. CNMI boat-based creel trolling CPUE (pounds/hour) for mahimahi

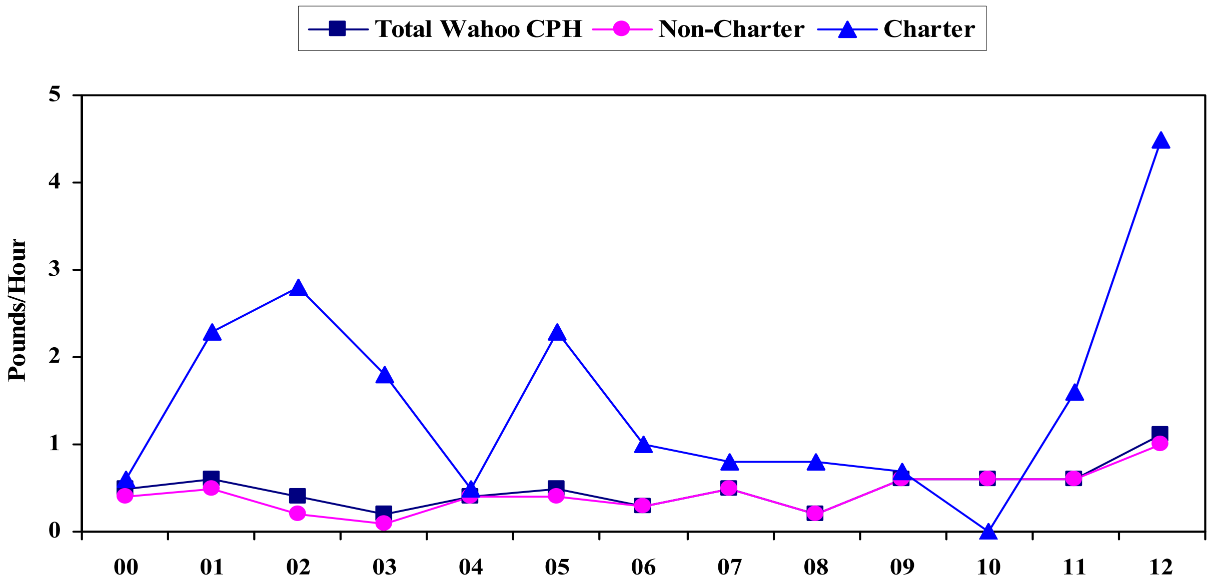


Interpretation: Mahimahi landing fluctuates yearly with high variability possibly due to seasonal availability of stocks and abundance. Mahimahi is not a very marketable fish on Saipan. Fishermen do not target mahimahi; therefore, varying catch rates can be expected. While non-charter vessels catch rates remained consistent from 2008 through 2011, charter vessel catch rate was low until a jump in 2011 to 3.8 lbs/hr. 2012 mahimahi catch rates decreased 23% from 2011 level. Non-charter mahimahi catch rates decreased 23% and charter catch rates decreased 36%.

CPUE (pounds/hour): Mahimahi			
Year	Combined	Non-Charter	Charter
2000	2.3	2.2	3.1
2001	2.2	2.1	4.6
2002	2.3	2.0	6.9
2003	1.4	1.3	2.3
2004	2.9	2.8	4.7
2005	2.3	2.1	4.6
2006	2.4	2.2	5.2
2007	5.2	5.0	11.7
2008	3.1	3.1	1.3
2009	3.0	3.1	1.7
2010	3.0	3.1	0.0
2011	3.0	3.0	3.9
2012	2.3	2.3	2.5
Average	2.7	2.6	4.0
Standard Deviation	0.8	0.9	2.8

Source and Calculations: Data are from the Division of Fish and Wildlife (DFW) boat-based creel survey. The data expansion system is run on a calendar year's worth of survey data to produce catch and effort estimates for each fishing method. This plot and table of catch per unit of effort (CPUE) are based on the total annual landings of mahimahi divided by the total number of hours spent fishing (gear in use).

Figure 42. CNMI boat-based creel trolling CPUE (pounds/hour) for wahoo

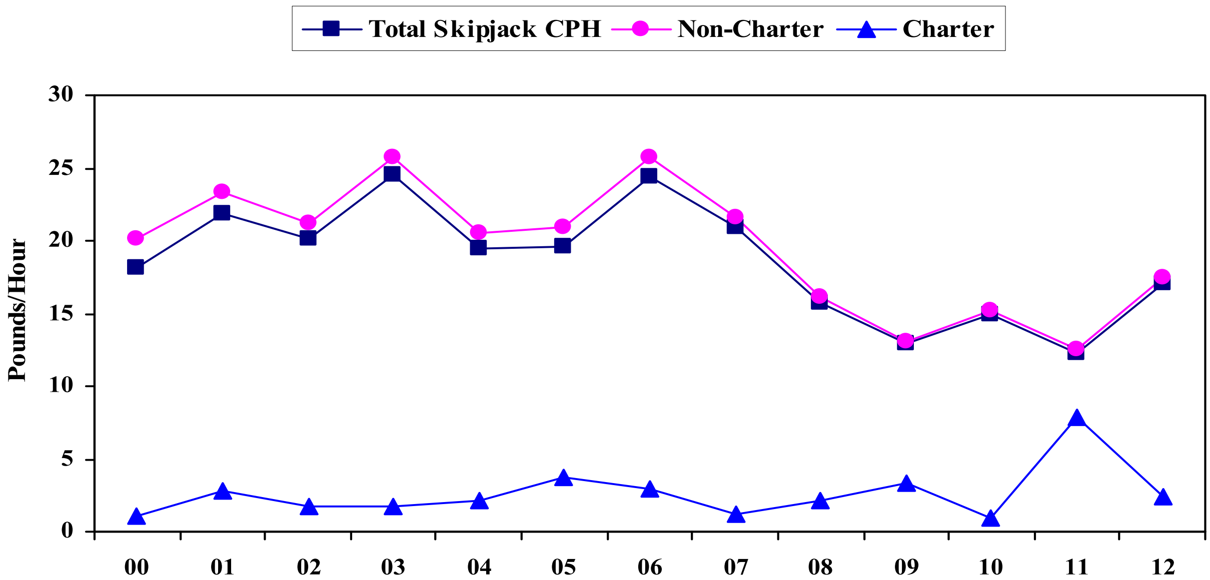


CPUE (pounds per hour): Wahoo			
Year	Combined	Non-Charter	Charter
2000	0.5	0.4	0.6
2001	0.6	0.5	2.3
2002	0.4	0.2	2.8
2003	0.2	0.1	1.8
2004	0.4	0.4	0.5
2005	0.5	0.4	2.3
2006	0.3	0.3	1.0
2007	0.5	0.5	0.8
2008	0.2	0.2	0.8
2009	0.6	0.6	0.7
2010	0.6	0.6	0.0
2011	0.6	0.6	1.6
2012	1.1	1.0	4.5
Average	0.5	0.4	1.5
Standard Deviation	0.2	0.2	1.2

Interpretation: The yearly fluctuation in wahoo catch rates is probably similar to Guam's wide fluctuations in their CPUE, possibly due to high variability in the year to year abundance and availability of the stocks. Catch rates for non-charter boats remained constant at 0.6 lbs/hr from 2009 to 2011, and increased 67% in 2012 to 1.0 lbs/hr. Catch rates fluctuated for charter vessels, with a significant increase from 2011 to 2012 of 1.6 lbs/hr to 4.5 lbs/hr, which is the highest catch rate recorded in 12 years. The combined non-charter and charter total wahoo catch rates remained constant at 0.6 lbs/hr from 2009 to 2011, and increased to 1.1 in 2012. The 2012 combined wahoo catch rates for non-charter and charter boats increased by 83%.

Source and Calculations: Data are from the Division of Fish and Wildlife (DFW) boat-based creel survey. The data expansion system is run on a calendar year's worth of survey data to produce catch and effort estimates for each fishing method. This plot and table of catch per unit of effort (CPUE) are based on the total annual landings of wahoo divided by the total number of hours spent fishing (gear in use).

Figure 43. CNMI boat-based creel trolling CPUE (pounds/hour) for skipjack tuna

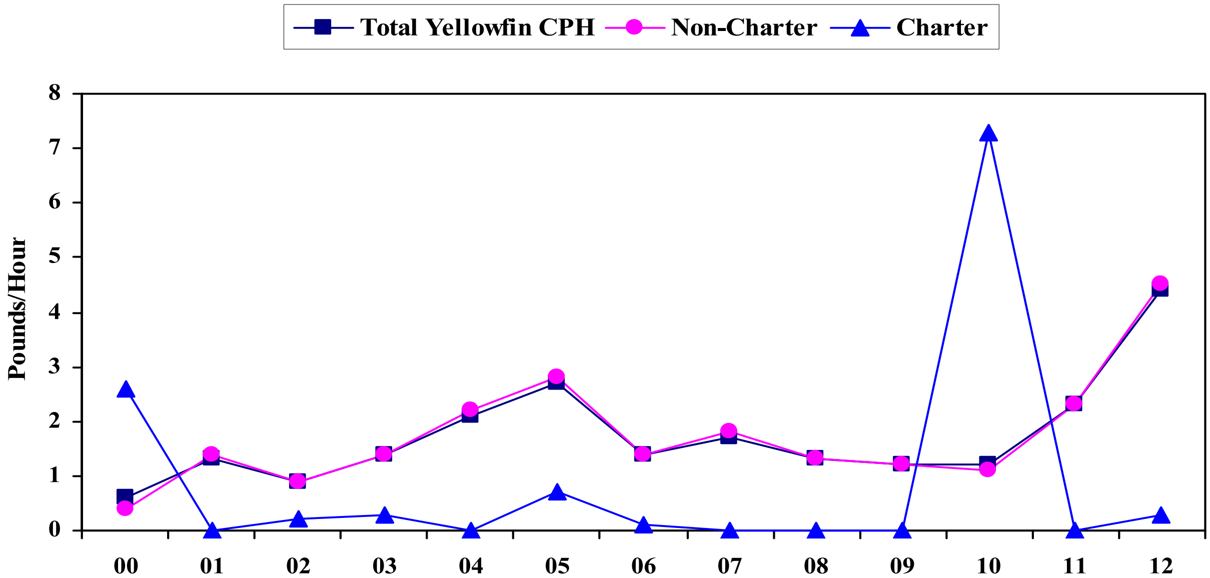


Interpretation: Skipjack tuna is the main targeted species in the pelagic fishery of the CNMI. Yearly fluctuations of catch rates may be due to availability of stock and the sea conditions; the smaller vessels typical for the commercial troll fishermen are affected more by unfavorable sea conditions. The combined catch rates for 2011 decreased 17% from 2010, but increased in 2012 by 39%. The non-charter boat catch rates for skipjack tuna, their primary target, decreased by 18% in 2011, but rebounded by 40% in 2012. Charter vessels showed a significant increase from 0.9 lbs/hr in 2010 to 7.4 lbs/hr in 2011, but decreased by 70% in 2012. Fishermen reported a better catch rate in 2012 than in 2011, which is also reflected in the shorter trips/hour that fishermen spent trolling.

CPUE (pounds/hour): Skipjack Tuna			
Year	Combined	Non-Charter	Charter
2000	18.1	20.1	1.1
2001	21.9	23.4	2.8
2002	20.2	21.2	1.7
2003	24.6	25.7	1.7
2004	19.5	20.5	2.1
2005	19.6	21.0	3.7
2006	24.4	25.7	3.0
2007	20.9	21.6	1.2
2008	15.7	16.1	2.1
2009	12.9	13.1	3.3
2010	14.9	15.2	0.9
2011	12.3	12.5	7.9
2012	17.1	17.5	2.4
Average	18.6	19.5	2.6
Standard Deviation	3.8	4.2	1.7

Source and Calculations: Data are from the Division of Fish and Wildlife (DFW) boat-based creel survey. The data expansion system is run on a calendar year's worth of survey data to produce catch and effort estimates for each fishing method surveyed. This plot and table of catch per unit of effort (CPUE) are based on the total annual landings of skipjack divided by the total number of hours spent fishing (gear in use).

Figure 44. CNMI boat-based creel trolling CPUE (pounds/hour) for yellowfin tuna



Interpretation: Yellowfin tuna landed on Saipan are usually smaller in size than other geographical areas. The average length of yellowfin tuna measured during creel survey sample days was around 48.7 cm. Fluctuations in yellowfin tuna catch rates are similar to mahimahi and wahoo in that it may have more to do with abundance and availability of stock. This species is seasonal in the CNMI. In 2011, non-charter fishermen reported a good year for landing yellowfin tuna, which is reflected in an increase in CPUE of 109%; there were no creel survey recorded landings of yellowfin tuna by charter vessels. In 2012, yellowfin tuna catch rates continued to increase by 96% over 2011 for non-charter boats; charter boats also experienced increased catch rates of 0.3 lbs/hr.

CPUE (pounds/hour): Yellowfin Tuna			
Year	Combined	Non-Charter	Charter

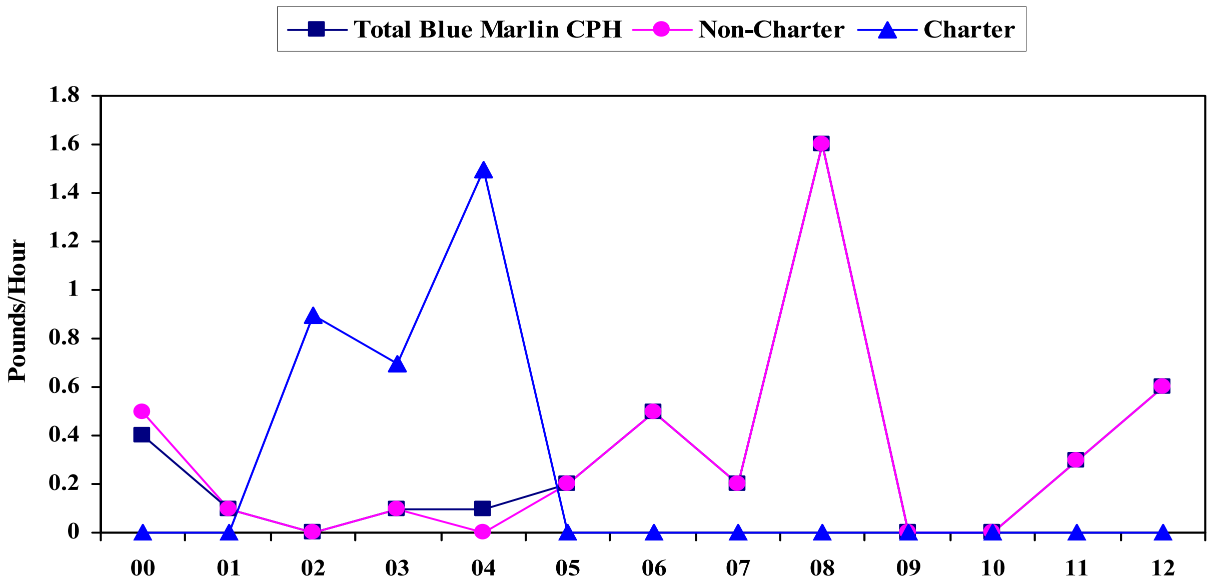
The data expansion system is run on a calendar year's worth of survey data to produce catch and effort estimates for each fishing method surveyed. This plot and table of catch per unit of effort (CPUE) are based on the total annual landings of yellowfin divided by the total number of hours spent fishing (gear in use).

Figure 45. CNMI boat-based creel trolling CPUE (pounds per hour) for blue marlin



Interpretation: Blue marlin is rarely a target for non-charter boats. There is almost no market for blue marlin and boats that make up the majority of the troll fishing industry are generally too small to transport blue marlins once they are landed. Blue marlins are mostly only targeted during fishing tournaments. Charter vessels target blue marlins, but trip time is limited. There have been no trips for blue marlins by charter vessels from 2005 through 2012. The non-charter catch rate increased from 2011 by 100% in 2012. Although there were landings recorded in the creel survey in 2012, blue marlin is rarely a target for non-charter boats and catch rates reported are more like an incidental catch rate.

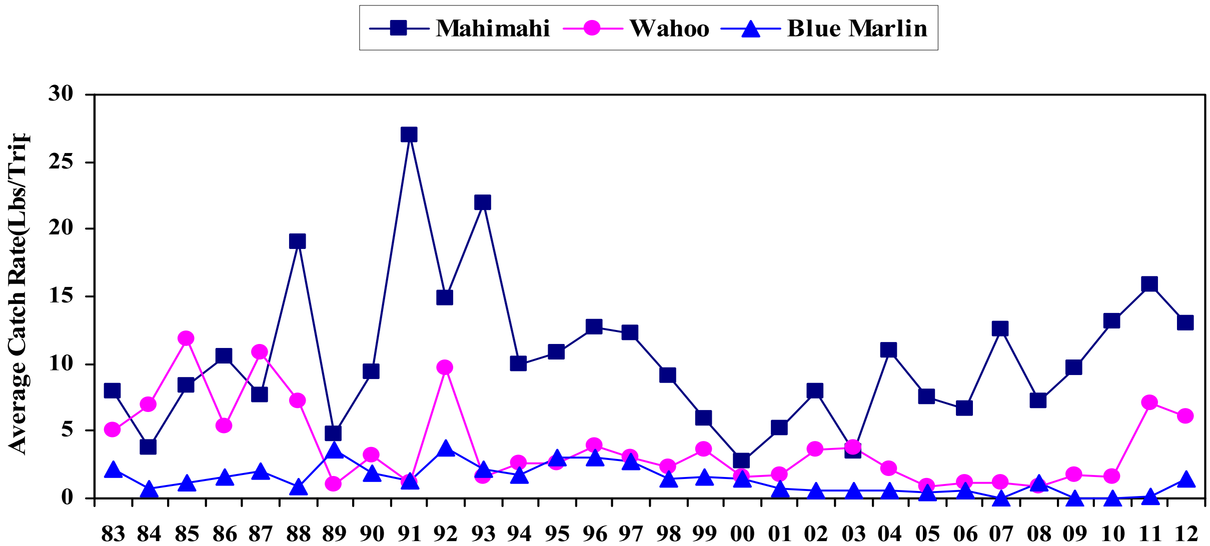
Calculations: The Commonwealth of the Northern Mariana Islands' Consumer Price Index is computed by the CNMI Department of Commerce using the Laspeyres' formula.

Figure 46. CNMI trolling catch rates from commercial receipt invoices for mahimahi, wahoo, and blue marlin (pounds/trip)



Interpretation: The mahimahi catch appears to be highly variable, shifting between high and low CPUE annually. It may be biological because it appears that the trolling catch rates of Guam and the CNMI have fluctuated similarly over the last twenty-nine years. Mahimahi catch rates increased steadily from 2008 through 2011, increasing 121%. It declined in 2012 though by 18%.

Prior to the 1989 record low, wahoo catch rates rivaled those for mahimahi. Wahoo catch rates generally never regained those historical levels. The record low was hit in 2008 at 0.91 lbs/trip. However, catch rates have increased steadily to the second highest level in 20 years, which were 7.00 lbs/trip in 2011 and 6.05 lbs/trip in 2012. 2012 was 13.5% lower than 2011.

Blue marlins are not a marketable species and are rarely a target by fishermen except during fishing tournaments. When landed, it is rarely sold to vendors participating in the Commercial Purchase Data Collection Program; therefore it would not be recorded in the Commercial Purchase Database used to generate these reports. During the 2000 Saipan International Fishing Derby, a 996-pound blue marlin was landed and another 997 pound blue marlin was landed in the 2011 fishing derby. However, blue marlin lbs/trip increased significantly in 2012. Large blue marlins are not uncommon around the waters of the CNMI however non-charter boats, which make up over 90% of the troll boat fleet, rarely, target this species.

Source and Calculations: Annual catch rates for selected species were obtained by calculating the average weight per trip for each year. Trips were assumed to be one day in length and each commercial invoice assumed to represent one trip.

Table 39. CNMI trolling catch rates from commercial receipt invoices for mahimahi, wahoo, and blue marlin (pounds/trip)

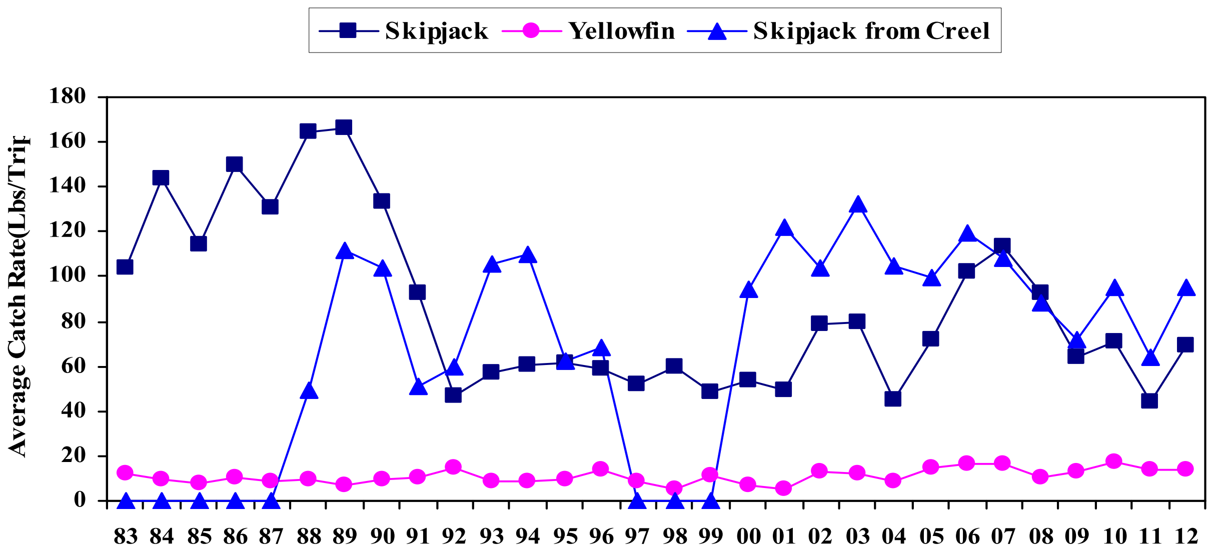
Standard Deviation	5.33	2.97	1.03

Figure 47. CNMI trolling catch rates from commercial receipt invoices for skipjack tuna, yellowfin tuna, and skipjack tuna from the Creel Survey (pounds/trip)



Interpretation: The Creel Survey data on skipjack tuna catch rates showed a very different pattern from the Commercial Purchase data until they appeared to stabilize beginning in 2006. Catch rates based on the Commercial Purchase Data Base and from the Creel Survey data continue a decline in 2011 that began in 2007, both showing a decline of about 30 lbs/trip since 2010. Previous discussions have suggested that non-tuna PMUS may be increasing in value and a slight shift in target troll fish may be occurring. The 2011 skipjack tuna catch rates decreased by 38 % from 2010 figures, but then increased 57% in 2012. This increase is partly due to better sea conditions.

Catch rates of yellowfin tuna per trip have been relatively consistent since 2005, varying between 13 and 17 lbs/trip, except a low of 10 lbs/trip in 2008. In 2011, the yellowfin tuna catch rate decreased by 3 lb/trip (18%) to 14 lbs/trip from the 2010 level, and remained the same in 2012 as indicated by commercial receipt invoices.

Source and Calculations: Data were summarized from the Commercial Purchase Database, which provides average pounds caught per trip. Annual catch rates for selected species were obtained by calculating the average weight per trip for each year. Trips were assumed to be one day in length and each commercial invoice represents one trip. Creel skipjack CPUE was calculated by dividing the sum of skipjack weight from all trolling trip interviews by the number of trolling trips interviewed.

Table 40. CNMI trolling catch rates from commercial receipt invoices for skipjack tuna, yellowfin tuna, and skipjack tuna from the Creel Survey (pounds/trip)

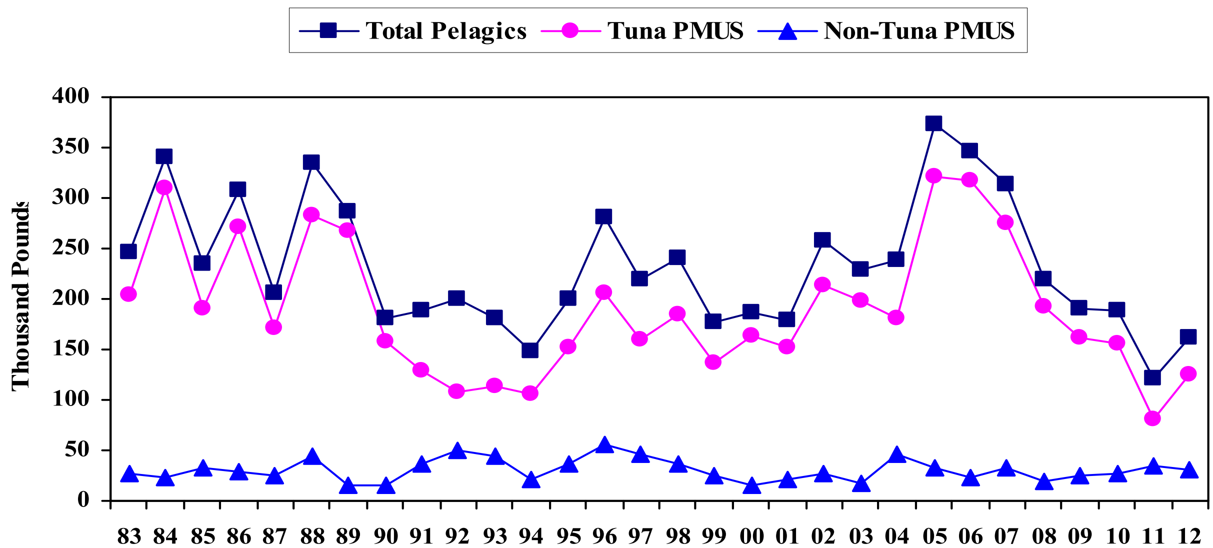
Average	86	11	67
Standard Deviation	37	3	45

Source and Calculations: Annual summaries for each species are from the Commercial Purchase Database invoices.

Figure 48. CNMI estimated total commercial landings (lbs) from commercial receipt invoices for tuna and non-tuna PMUS



Interpretation: The total pelagics landed in 2012 increased 33% despite landings in 2011 decreasing by 40% from 2010. Tuna PMUS landing also increased in 2012 by 54% but still lower than the 30 year mean. Non-tuna PMUS landings decreased in 2012 by 14%. The current downward trend of the CNMI economy has been very challenging for fish vendors to stay open. Fluctuations in total pelagic landings are mostly due to the low demand for troll fish in the CNMI.

Source and Calculations: All pelagics, tuna and non-tuna PMUS landings were summed from the Commercial Purchase Database.

Table 41. CNMI estimated total commercial landings (lbs) from commercial receipt invoices for all pelagic, tuna, and non-tuna PMUS

CNMI Estimated Total Commercial Landings			
Year	All Pelagics	Tuna PMUS	Non-Tuna PMUS

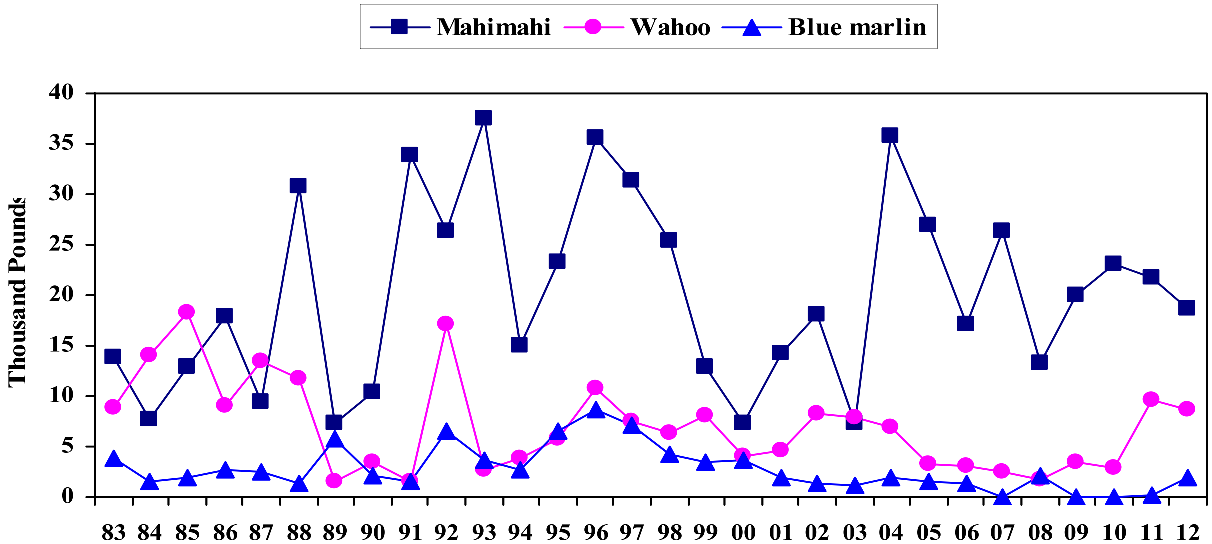
Standard Deviation	63,274	65,157	10,668

Figure 49. CNMI estimated commercial landings from commercial receipt invoices for mahimahi, wahoo, and blue marlin



Interpretation: Mahimahi has been on a downward trend from 2010 through 2012. Mahimahi landings decreased by 16% from 2010 to 2011, and 1% from 2011 to 2012. However, this is after an upward trend from 2008 through 2010 in which mahimahi increased 48% then 16%. It is noteworthy that the CNMI and Guam mahimahi catches have been fluctuating similarly since 1987, which may indicate a strong biological influence in local landing patterns.

Wahoo landings were relatively stable, although low, from 2005 through 2010. Wahoo landings in 2011 showed a significant increase in landings, from 2,887 pounds in 2010 to 9,606 pounds in 2011, a 230% increase. Fishermen have reported that they fished closer to land and near reefs to lower fuel cost which may be attributed to increase in wahoo landings. Wahoo landings in 2012 declined slightly by 10%. Yearly fluctuations with wahoo landings are not unusual for the CNMI since fishermen mainly target skipjack tuna.

Blue marlin is rarely a target by the commercial fishermen except for charter boats and during fishing tournaments. If blue marlins are landed, they are often kept by the fishermen and therefore rarely ever recorded in the Commercial Purchase Data Base. 2009 through 2011 landings were very low (<175 lbs), but in 2012 there was over 2,000 pounds of blue marlin recorded as being sold, a level not seen since 2008 and prior to that, in 2004.

Source and Calculations: The annual commercial landings of the three major PMUS species (mahimahi, wahoo and blue marlin) were summed directly from the Commercial Purchase Database.

Table 42. CNMI estimated commercial landings for mahimahi, wahoo, and blue marlin

Estimated Commercial Landings			
Year	Mahimahi	Wahoo	Blue Marlin
1983	13,939	8,760	3,787
1984	7,614	14,087	1,544

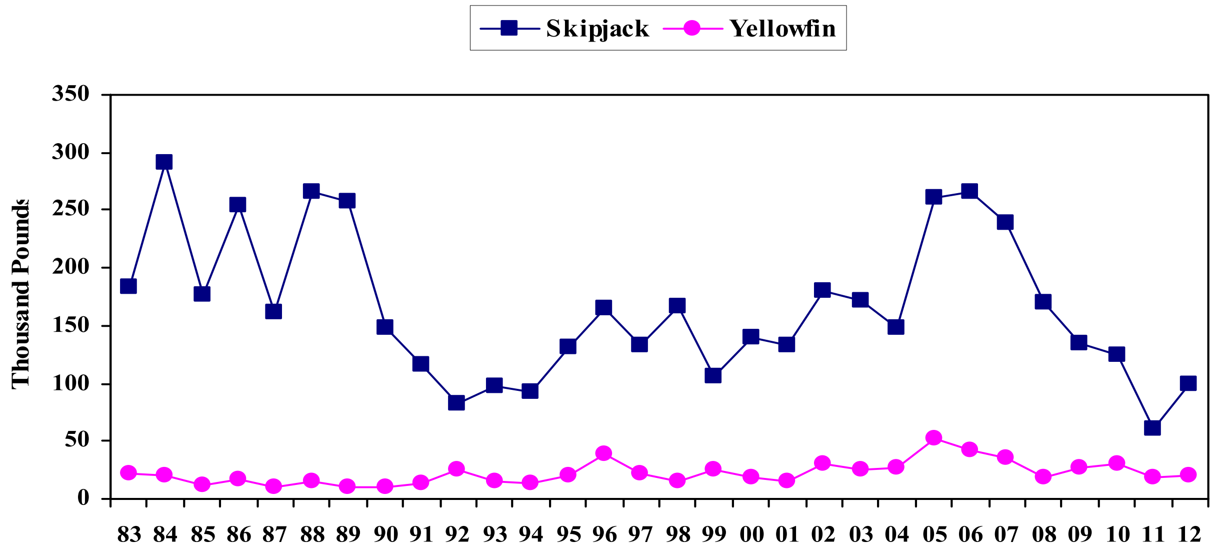
Figure 50. CNMI estimated commercial purchase database landings from commercial receipt invoices for skipjack tuna and yellowfin tuna



Interpretation: Skipjack tuna was on a steady decline from 2006 through 2011 as a result of the current downward trend of the CNMI economy and also lack of vendor participation in this voluntary program. Sea conditions were also not favorable in 2011. The demand for pelagic fish is not what it once was. In 2012, skipjack landings recovered slightly by 64%. Fishermen reported better catch rates and better sea conditions in 2012.

Although more highly prized than skipjack, yellowfin tuna are not as common, and therefore not landed as often. The average fish size tends to be smaller when compared with yellowfin tuna from other geographic areas. Landings decreased steadily from 2005 through 2008, recovered somewhat over 2009 and 2010, but then decreased by 37% in 2011, partially due to some vendors not participating in this voluntary program. Landings remained steady in 2012, increasing only 2%. This increase is due to better participation by vendors in this data collection program as well as an increase in yellowfin tuna landings, as indicated in the creel survey program.

Source and Calculations: Landings were summed directly from the Commercial Purchase Database.

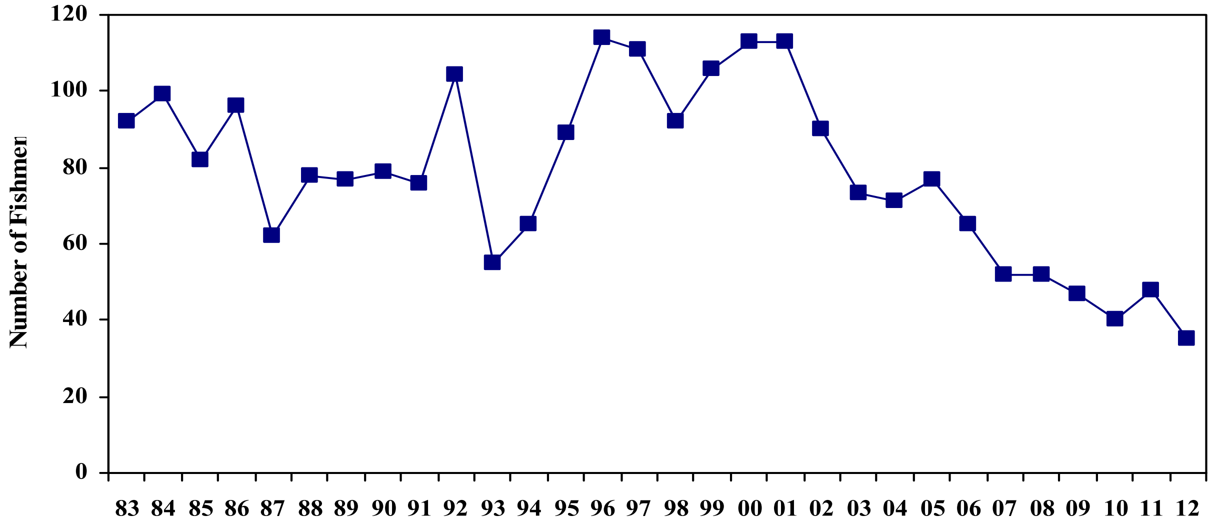
Figure 51. CNMI number of commercial vessels landing pelagic species from commercial receipt invoices



Interpretation: The number of fishers (vessels) making pelagic landings has been steadily decreasing from 2001 through 2012, despite a slight increase in 2011 of 17%. In 2012, the number of fishers declined 27% from 2011. The decrease is partly due to vendors who own multiple fishing boats entering all their landings on a single receipt and at times combining monthly total landings onto a single receipt. Other factors that may have influenced a drop in fishermen making pelagic landings are the bad weather that plagued the Marianas throughout 2003 and early 2004, continued increase in fuel price, continued decline in the average price per pound of skipjack tuna, and downward trend in the CNMI economy. Also, several long-time fishermen have left the fishery.

Source and Calculations: Each invoice from the Commercial Purchase Database records the fisherman's name from whom the fish were purchased. The number of fishermen who sold any pelagic species was calculated directly from the data invoices.

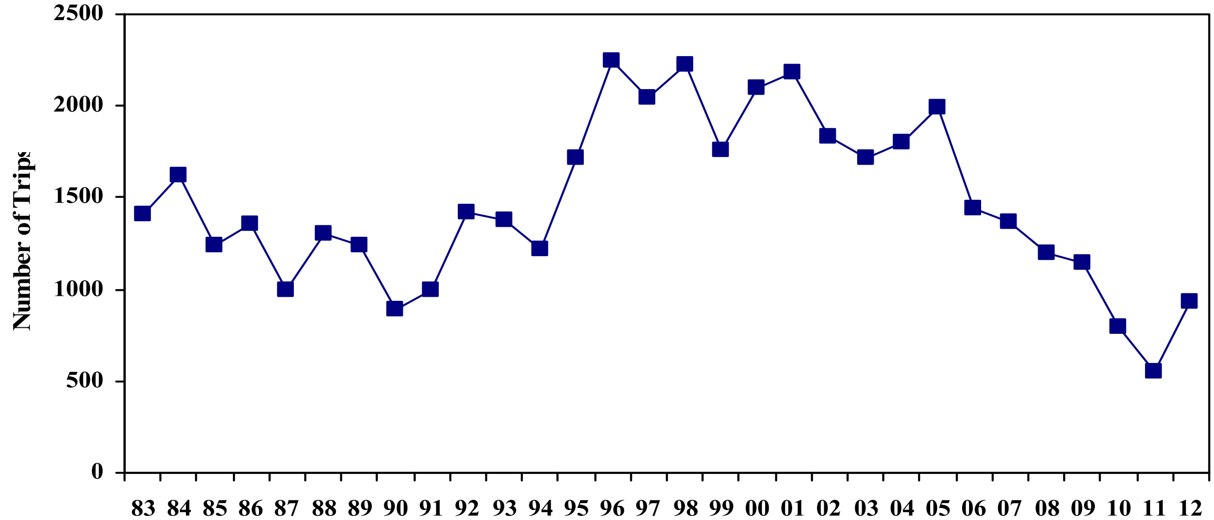
Figure 52. CNMI number of fishing trips commercially landing any pelagic species from commercial receipt invoices



Interpretation: Despite a slight upward trend in 2004 and 2005, there has been a continued decline in the number of fishing trips commercially landing pelagic species since 2001. The decline in the number of trips from 2005 to 2009 is related to the lack of market demand for pelagics. Typhoons hit the Marianas region frequently, which may contribute to some decline in fishing trips, as well as the increasing price of fuel cost ($3.58/gallon in 2006 compared to $4.33/gallon in 2007). The decline in 2010 and 2011 may be partly due to the lack of requirements of vendors and fishermen to participate in this commercial receipt invoice program. However the CNMI Division of Fish and Wildlife (DFW) are currently trying to implement a legislative requirement to address this issue. In 2012, DFW started to actively encourage fish vendors to participate in this program. With this determined new effort to have better commercial receipt invoice data coverage, the number of fishing trips reported in this program increased by 70%.

Source and Calculations: The total trips for all pelagic species were summed from the Commercial Purchase Database. Trips were calculated based on the assumptions that no fisherman makes more than one trip per day, and that all sales from a single trip are made on a single day.

Table 45. CNMI Number of fishing trips commercially landing any pelagic species

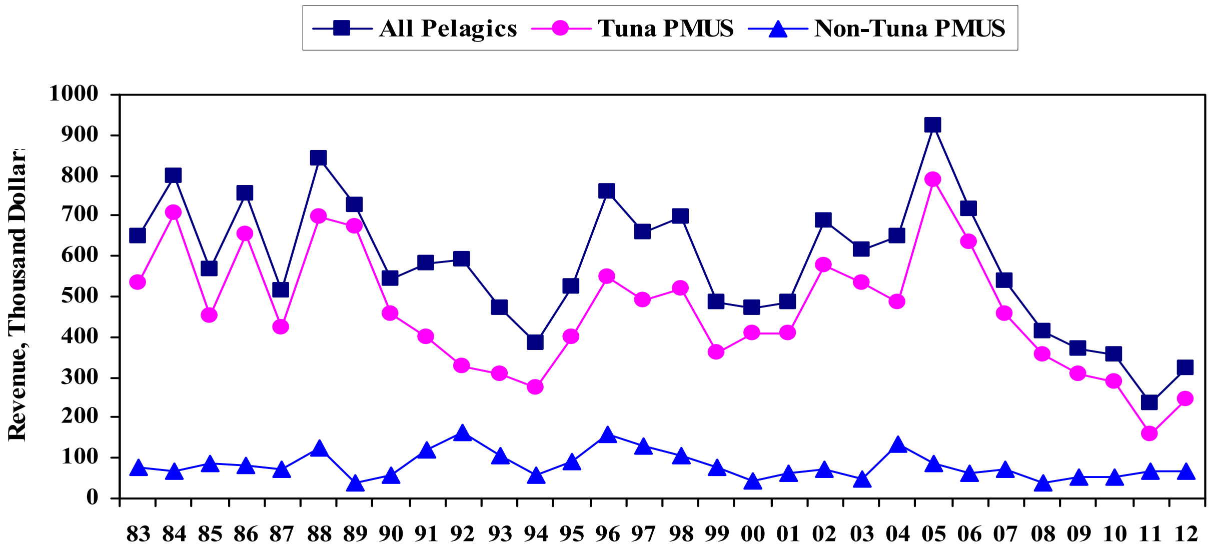
Figure 53. CNMI annual adjusted commercial revenues from pelagic species obtained from commercial receipt invoices



Interpretation: The erratic fluctuations of the inflation-adjusted revenues for tunas and for all pelagics prior to 1990 is most likely due to the annual variations in skipjack tuna landings, which completely dominated the tuna category and the "All Pelagics" category. In 2003, the tunas' inflation-adjusted revenues decreased 8% from the 2002 figures and continued to decline to 11% for 2004. This is due to the decrease in landings of skipjack tuna, which in 2004 comprised only of 67% of the total pelagic landings compared to 2003 where it comprised 87% of the total pelagic landings. The tunas' inflation-adjusted revenues increased significantly by 38% in 2005, but have steadily declined since. According to vendors, these declines are due to the low demand for pelagic or troll species. This decrease in tuna adjusted revenues continued annually from until 2012, when revenues increased 56% over 2011. This increase in revenue is due to an increase in landings and better data coverage in this program.

In 2003, a drop of 31% occurred for the non-tuna PMUS inflation-adjusted revenues, however 2004 data indicates an increase of 158% compared to the previous year because mahimahi landings increased by 387%. The inflation adjusted revenue decreased from 2004 through 2008, but increased in 2009 by 25%. The inflation adjusted revenue increased again in 2010 and 2011, but declined in 2012 by 5%.

The 2010 inflation adjusted revenues for all pelagic declined slightly and declined further in 2011. The decline in 2010 is related to the decreasing price per pound for pelagics and decline in total landings that is reported on the commercial receipt invoice program. In 2012, the inflation adjusted revenue for all pelagics increased by 39%.

Source and Calculations: Annual revenue in dollars was summed separately for all pelagic fish, tunas and non-tuna PMUS. Inflation-adjusted revenues were calculated using the Consumer Price Index, with 1998 as a base by which previous years' nominal prices are adjusted.

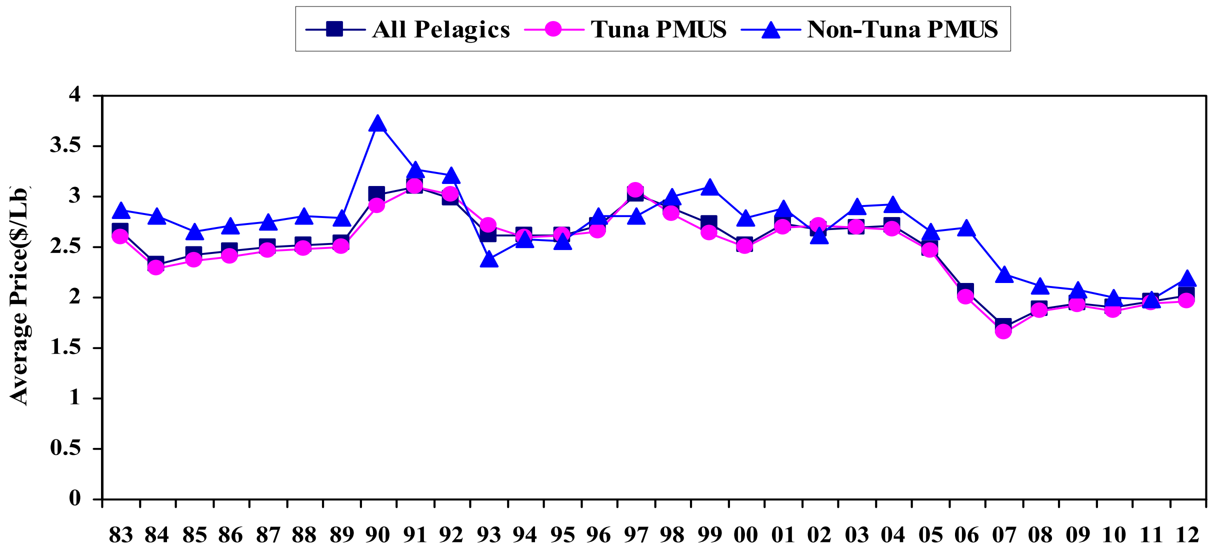
Figure 54. CNMI average inflation-adjusted price for commercially landed pelagic species (dollars per pound)



Interpretation: The inflation-adjusted average price of all pelagic declined steadily from 2004 to 2007, but recovered some in 2008 by 10%. The price remained stable from 2008 through 2011, fluctuating between $1.84 and $1.95. In 2012, the price increased by 4% to $2.02.

The inflation-adjusted average price of tuna declined steadily from 2002 through 2007, but recovered slightly in 2008 by 13%. It has fluctuated between $1.86 and $1.96 since, with the high of $1.96 in 2012, a 0.5% increase over 2011.

Decline in price per pound for skipjack tuna is a direct result from strong competition among fishermen. Fishermen land large amounts of skipjack tuna, flooding markets and consequently causing prices to drop as low as $.75 per pound. This saturation of the local markets directly affects both the inflation-adjusted average prices and the inflation-adjusted revenues. In 2011 and 2012 there were far fewer fishermen participating in the troll fishery than in previous years.

The average for the inflation-adjusted price of non-tuna PMUS increased to $2.90 in 2003 and remained at near that level for 2004. However, the price has steadily decreased since 2005 through 2011, when the adjusted average price per pound reached $1.98. In 2012, inflation adjusted price per pound for non-tuna PMUS increased 11%, recovering slightly to $2.19.

Source and Calculations: The unadjusted average price is calculated by dividing the total revenues generated by the total weight sold. The inflation adjustment is made using the 1998 NMI Consumer Price Index (CPI) as the basis by which calculations of previous years' prices are made.

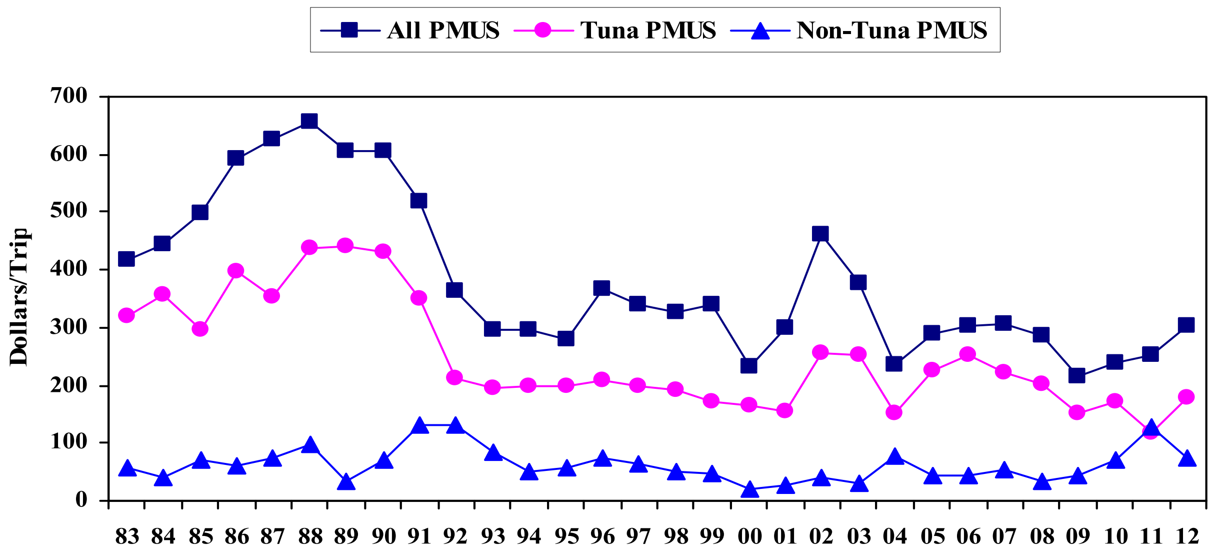
Figure 55. CNMI per-trip adjusted revenues for commercially sold pelagic species from commercial receipt invoices



Interpretation: The inflation-adjusted revenue per trip for all species increased 20% in 2012. Although fishermen earned the same price pound in 2012 and 2011 for skipjack tuna, the average price for other non-tuna species increased. 2012 tuna PMUS inflation-adjusted revenue increased significantly by 52%. This is possibly due to fishermen getting better pricing for yellowfin tuna. In 2012, non-tuna PMUS per trip adjusted revenue declined 43%.

Source and Calculations: Values were obtained by selecting, from the Commercial Purchase Database, all trips which landed at least one PMUS, and then calculating a) the average revenue of all species combined, b) the average revenue of non-tuna PMUS only, and c) the average revenue of tuna only.

Table 49. CNMI non-charter and charter trolling bycatch summary based on interview catch data, 2000-2012

		Number Caught					Trip		
	Species	Released	Dead/Injd	Both	All	BC%	With BC	All	BC%
Non Charter							3	1,876	0.16
	Mahimahi	4		4	3,136	0.13			
	Yellowfin Tuna		1	1	2,398	0.05			
	Skipjack Tuna	1		1	43,842				
	Total			6	49,376	0.01			
	Compared With All Species			6	52,620	0.01			
Charter							0	207	0.00
	Compared With All Species						0	1,081	0.00

Interpretation: With the assistance of NMFS staff, the implementation of an Offshore Day Time Creel Survey program began in April 2000. One of the main purposes of re-implementing the Offshore Creel Survey was to address the issue of bycatch. This bycatch summary data is not expanded.

A summary report from the year 2000 to 2012 by both non-charter and charter boats indicates less than 1%, or 6 out of 49,376, of the total pelagic species landed is released. Only three species were reported as bycatch: mahimahi, yellowfin tuna and skipjack tuna. Four out of 3,136 (0.13%) mahimahi landed were released. One out of 2,398 (0.04%) yellowfin tuna landed was released. There was 1 out of 43,842 skipjack tuna recorded as released. Charter boats had no bycatch reported.

Bycatch in the CNMI has been believed in the past not to exist because fishermen retain most of their catch, which is further supported by the results of the Offshore (Boat Based) Creel Survey. The CNMI will continue sampling in order to monitor this issue however it is a common practice by fishermen to keep all species caught regardless of size, species or condition.

Source: Offshore (Boat Based) Creel Survey Expansion Program.

C. Guam

Introduction

Pelagic fishing vessels based in Guam are classified into two general groups: 1) distant-water purse seiners and longliners that fish outside Guam's economic exclusive zone (EEZ) and transship through the island and, 2) small recreational trolling boats that fish only within local waters, either within Guam's EEZ, or occasionally, in Commonwealth of the Northern Mariana Islands (CNMI) waters. Primarily, this module covers the Guam-based small-boat pelagic fishery.

The estimated annual pelagic landings have varied widely, ranging between 322,000 and 937,000 pounds over the 30-year time series. The average total catch has shown a slowly increasing trend over the time period. The 2012 total pelagic landings were approximately 495,384 pounds, a decrease of 16% compared with 2011. Landings consisted primarily of five major species: mahimahi (*Coryphaena hippurus*), wahoo (*Acanthocybium solandri*), bonita or skipjack tuna (*Katsuwonus pelamis*), yellowfin tuna (*Thunnus albacares*), and Pacific blue marlin (*Makaira mazara*). Other minor catch species include rainbow runner, dogtooth tuna, barracudas, and sailfish. No sharks were encountered during creel surveys in 2012. While sailfish are kept, sharks are often discarded as bycatch. In addition to the above pelagic species, kawakawa and pomfrets were landed incidentally this year.

The number of boats involved in Guam's pelagic or open ocean fishery gradually increased from 193 in 1983 to 469 in 1998. This number decreased until 2001, but has generally been increasing since that year. There were 351 boats involved in Guam's pelagic fishery in 2012, a decrease of 23% from 2011. A majority of the fishing boats are less than 10 meters (33 feet) in length and are usually owner-operated by fishermen who earn a living outside of fishing. Most fishermen sell a portion of their catch at one time or another and it is difficult to make a distinction between recreational, subsistence, and commercial fishers. A small, but significant, segment of the pelagic group is made up of marina-berthed charter boats that are operated primarily by full-time captains and crews. Data and graphs for non-charters, charters, and bycatch are represented in this report.

There are general wide year-to-year fluctuations in the estimated landings of the five major pelagic species. Most catch amounts for the five common species showed decreases from 2011 levels. 2012 mahimahi catch decreased 7% from 2011, wahoo catch increased 19.5% from 2011, skipjack (bonita) catch decreased by 10.5% from 2011, Pacific blue marlin catch decreased 33% from 2011, and yellowfin tuna catch decreased 64% from 2011.

Aggregate landings of all pelagics, tuna, and non-tuna Pelagic Management Unit Species (PMUS) decreased in 2012 from 2011 levels. Landings of all pelagics decreased 16%, with tuna PMUS decreasing 20% and non-tuna PMUS decreasing 2%. The number of trolling boats decreased by 23%, the number of trolling trips decreased by 26%, and hours spent trolling decreased by 30%. Total CPUE increased 13%. Mahimahi, wahoo, and skipjack CPUE increased; blue marlin remained constant; and yellowfin tuna CPUE decreased.

Commercial landing data for 2012 decreased from 2011 levels. Commercial landings and revenues decreased in 2011, with total adjusted revenues decreasing 15%. The adjusted average price per pound for tuna PMUS decreased by 3%, and non-tuna PMUS decreased by only 0.9%. Adjusted revenue per trolling trip decreased 5% for all pelagics, increased 36% for tuna PMUS, and decreased 7% for non-tuna PMUS. Commercial landings have shown a decreasing trend over the past ten years. A majority of troll fishermen do not rely on the catch or selling of fish as their primary source of income. Previously, Guam law required the government of Guam to provide locally caught fish to food services in government agencies, such as Department of Education and Department of Corrections. In 2002, the government of Guam began implementing cost-saving measures, including privatization of food services. The requirement that locally-caught fish be used for food services, while still a part of private contracts, is not being enforced. This has allowed private contractors to import cheaper foreign fish, and reduced the sales of vendors selling locally caught fish. This represented a substantial portion of sales of locally caught pelagic fish. The decrease in commercial sales seen following 2002 may be, in part, due to this change.

In early 2010, the U.S. military began exercises in an area south and southeast of Guam designated W-517. W-517 is a special use airspace (SUA) (approximately 14,000 nm^2) that overlays deep open ocean approximately 50 miles south-southwest of Guam. Exercises in W-517 generally involve live fire and/or pyrotechnics. When W-517 is in use, a notice to mariners (NTM) is issued, and vessels attempting to use the area are advised to be cautious of objects in the water and other small vessels. This discourages access to virtually all banks south of Guam, including Galvez, Santa Rosa, White Tuna, and other popular fishing areas. From 1982-2009, DAWR surveys recorded more than 2020 trolling and bottom fishing trips to these southern banks, an average of more than 72 trips per year. During 2012, 32 NTM comprising a total of 72 days (19.7% of all days) were issued for area W-517. This makes access to these banks less attractive fishing areas for nearly 1/5th of the year. Additionally, the military occasionally holds exercises that do not involve live fire, but still restricts access to the area. As no notice is given for these events, there is not a reliable way to track how frequently this occurs.

The shortage of staff biologists has been significant in the past several years. DAWR staff biologists continue to oversee several projects simultaneously, while providing on-going training to ensure the high quality of data being collected by all staff. All fisheries staff are trained to identify the most commonly caught fish to the species level. New staff are mentored by biologists and senior technicians in the field before conducting creel surveys on their own.

The makeshift ramp at Ylig Bay was eliminated in 2010. Widening of the main road on the south east coast of Guam will cause removal of the ramp. In December 2006, a new launch ramp and facility was opened in Acfayan Bay, located in the village on Inarajan on the southeast coast of Guam. Monitoring of this ramp for pelagic fishing activity began at the start of 2007. In early 2007, this facility was damaged by heavy surf and has yet to be repaired. Monitoring of this ramp is currently on hold until the ramp is repaired. The current financial situation for the Guam government makes it unlikely this ramp will be repaired in the near future. With the loss of the Ylig ramp and the destruction of the ramp in Acfayan Bay, there will be no boat launching facilities on the east side of Guam.

Four FADs were deployed in 2012. DAWR currently is ordering 5 more systems, and is awaiting the awarding of a deployment contract. If these five systems are deployed, this should bring the number of FADS on station to 13, of the fourteen considered to be a full complement.

Plan Team Recommendations

There were no 2012 Plan Team recommendations.

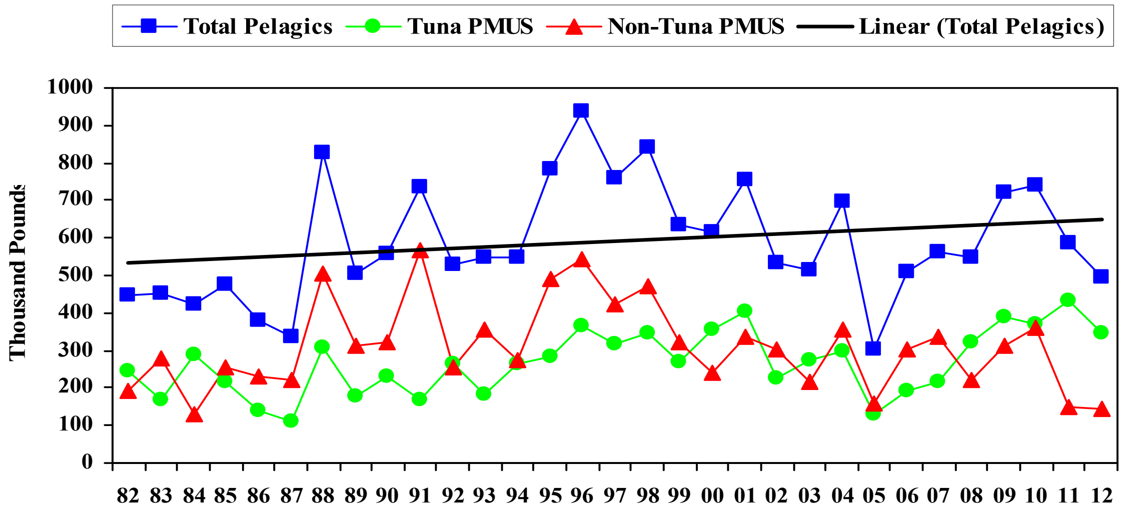
Figure 56. Guam annual estimated total landings: all pelagics landings, tuna PMUS landings, and non-tuna PMUS landings



Interpretation: The estimated pelagic landings have been cyclic with alternating high and low multi-year periods and annual variation within those smaller time periods. Total pelagic catch peaked in 1996 and reached an historic low in 2005. Landings rose in 2009 and 2010, but returned to 2006-2008 levels for 2011 and 2012. Factors relating to this cycle may be associated with the biology of the fish or be weather related. There is also evidence from the fishermen and historic creel survey data that some pelagic fish species are not caught consistently year round around Guam.

Total pelagic and tuna PMUS decreased in 2012 by 16% and 20% respectively, compared with 2011, while non-tuna landings decreased only 2%. Non-tuna PMUS catch was well below the 30 year average, while the tuna PMUS catch was above the 30 year average. Total catch was also below the 30 year average. Generally, skipjack tuna are consistently caught year round, with the other major pelagic species being more seasonal. There is now a small fleet of vessels targeting skipjack tuna. These vessels fish almost every day, which is contributing to the high levels of tuna catch.

Source and Calculation: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel survey. A 365-day (366 days during leap years) quarterly expansion is run for each calendar year of survey data to produce catch and effort estimates for the pelagic fishery to avoid over-estimating seasonal pelagic species. Percent species composition is calculated by weight for the sampled catch for each method to produce catch estimates for each species for the expanded period. The annual catch for all pelagic species and the PMUS separately are summed across all methods to obtain the numbers plotted above.

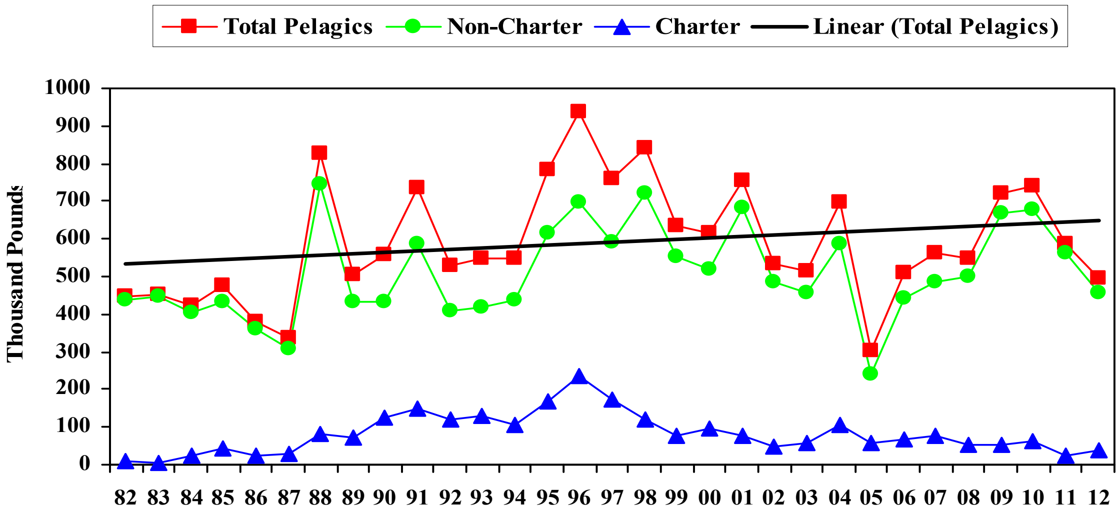
Figure 57. Guam annual estimated total landings: total pelagics landings, non-charter landings, and charter landings



Interpretation: Non-charter trolling trips have always accounted for the bulk of the pelagic catch, although charter boats, which make up less than 5% of the troll fleet, account for a high proportion of trolling effort and catch. Prior to 1988, non-charter boats accounted for over 90% of the troll catch. In 1988, this percentage decreased due to an increase in charter boat activity catering specifically to Asian visitors. Beginning in 1996 however, a downturn in Japan's economy caused a significant decrease in charter trips and subsequent landings. No such trend is observed for non-charters. In 2012, non-charter landings decreased 19%, while charter landings increased 52%. Non-charter boats landed 86% of all pelagics in 2012.

Source and Calculations: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel survey data. A 365-day (366 days during leap years) quarterly expansion is run for each calendar year of survey data to produce catch and effort estimates for trolling. Percent species composition is calculated by weight for the sampled catch for each method to produce catch estimates for each species for the expanded period. The annual catch for all pelagic species and the PMUS separately are summed across all methods to obtain the numbers plotted above.

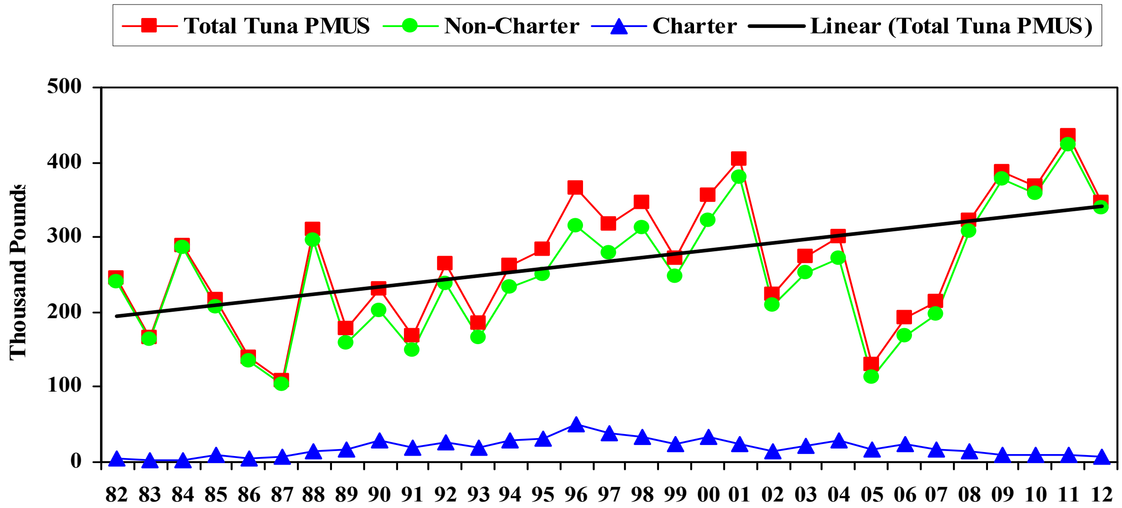
Figure 58. Guam annual tuna PMUS landings: total landings, non-charter landings, and charter landings



Interpretation: The general trend of the estimated total tuna landings is increasing. Non-charter boats account for the bulk of the total tuna catch. In 2012, 93% of tuna were caught by non-charter boats. 2012 non-charter landings decreased by 20%, and charter landings decreased by 35%. The 2012 estimated tuna PMUS landings were 30% higher than the 30 year average.

Source and Calculations: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program, expanded with the assistance of NMFS. A 365-day (366 days during leap years) quarterly expansion is run for each calendar year of survey data to produce catch and effort estimates for trolling. Percent species composition is calculated by weight for the sampled catch for each method to produce catch estimates for each species for the expanded period. The annual catch for all pelagic species and the PMUS separately are summed across all methods to obtain the numbers plotted above.

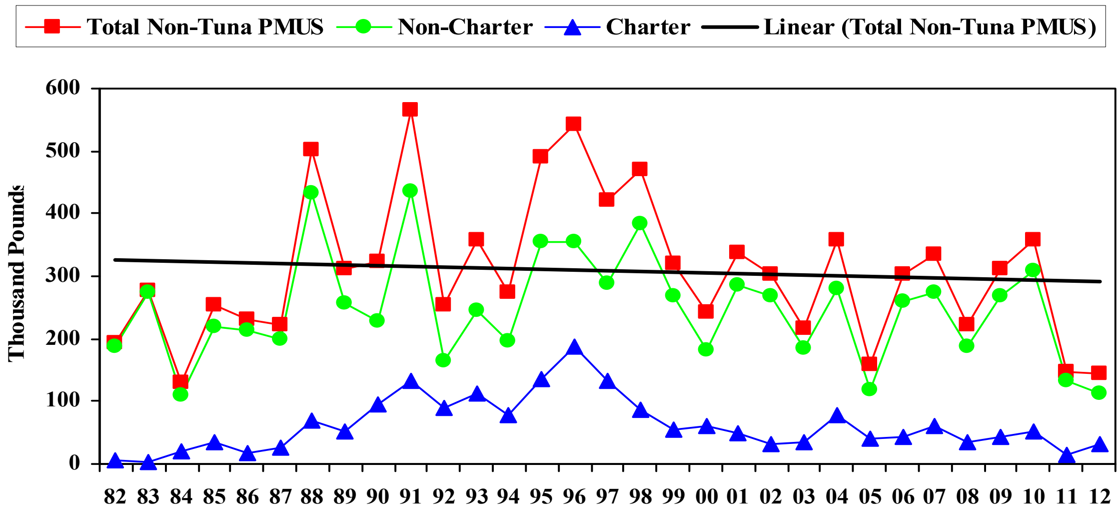
Figure 59. Guam estimated non-tuna PMUS landings: total landings, non-charter landings, and charter landings



Interpretation: The estimated total non-tuna PMUS landings showed a general increase between 1984 and 1996, corresponding with an increase in boats entering the fishery. However, the non-tuna PMUS landings have been experiencing a general decline over the last 30 years. Non-charter trolling trips accounts for the bulk of the non-tuna PMUS catch. In 2012, total non-tuna PMUS and non-charter non-tuna PMUS decreased 2% and 15% respectively compared to 2011. However, charter non-tuna PMUS increased 116%. These decreased levels may be due to the biology of non-tuna PMUS species, primarily mahimahi. Additionally, poor weather conditions limited the number of fishing days in 2011. Non-charter boats accounted for 78% of non-tuna PMUS catch in 2012.

Source and Calculation: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program, expanded with the assistance of NMFS. A 365-day (366 days during leap years) expansion is run for each calendar year of survey data to produce catch and effort estimates for each fishing method surveyed. Percent species composition is calculated by weight for the sampled catch for each method to produce catch estimates for each species for the expanded period. The annual catch for all pelagic species and the PMUS separately are summed across all methods to obtain the numbers plotted above.

Table 56. Guam annual boat-based creel estimated non-tuna PMUS landings: total, non-charter vessels, and charter vessels (pounds)

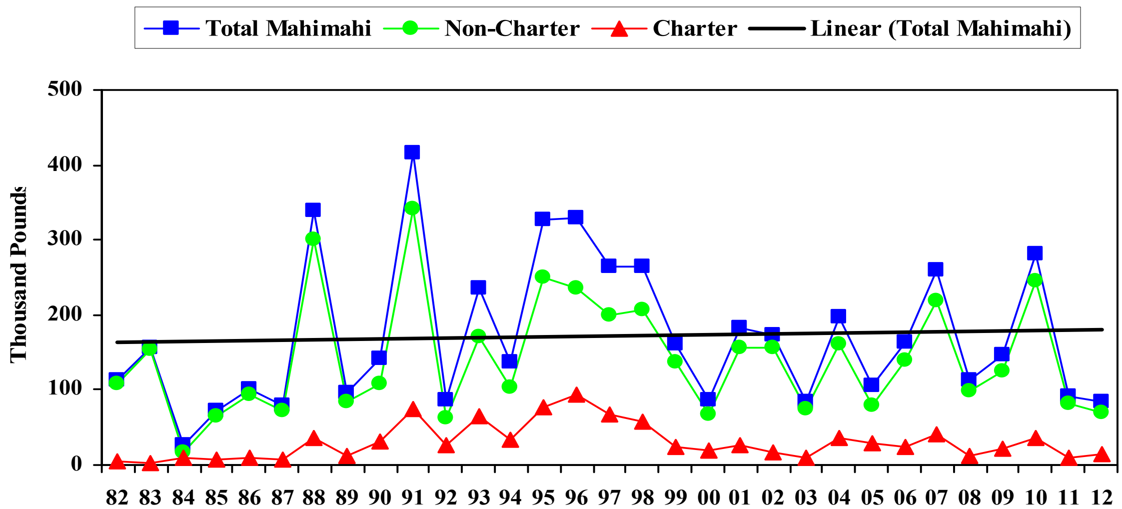
Figure 60. Guam annual estimated mahimahi landings: total landings, non-charter landings, and charter landings



Interpretation: Historically, mahimahi catches have fluctuated wildly, with a good year followed by one or two down years. Catch peaked in 1996, and has been lower since, although still demonstrating the cyclical nature. Non-charter trips account for the bulk of the mahimahi catch, with charter activity harvesting proportionally more beginning in the late 1980s as tourist arrivals to Guam increased. A drop in charter catch corresponds to decreasing tourist arrivals in the late 1990s. In 2012, total and non-charter mahimahi landings decreased 7% and 16%, respectively. Charter landings increased by 69%. All three categories are well below the 30 year average.

Source and Calculations: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files, expanded with the assistance of NMFS. Totals by species are summed across all fishing methods as described in Figure 56 through Figure 59.

Table 57. Guam annual estimated mahimahi landings: total, non-charter landings, and charter landings (pounds)

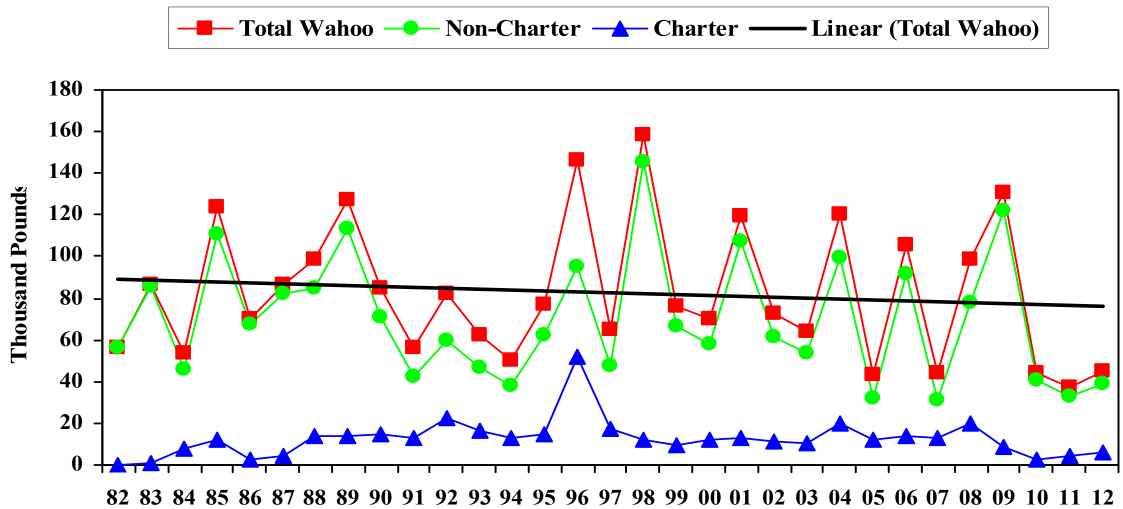
Figure 61. Guam annual estimated wahoo landings: total landings, non-charter landings, and charter landings



Interpretation: The wide fluctuations in wahoo landings are probably due to the high variability in the year-to-year abundance and availability of the stocks. Until 1987, non-charter landings accounted for over 95% of the total catch. In 1988, this percentage decreased due to an increase in charter boat activity. In 1996, wahoo charter landings peaked, accounting for 35% of the total catch. Wahoo charter landings remained relatively stable through 2009, but have been low the last three years. In 2012, total, charter, and non-charter wahoo landings increased 20%, 26%, and 19%, respectively. Charter landings only represent 13% of the total wahoo landings. The total wahoo catch was 50% below the 30 year average.

Source and Calculations: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files, expanded with the assistance of NMFS. Totals by species are summed across all fishing methods as described in Figure 56 through Figure 59.

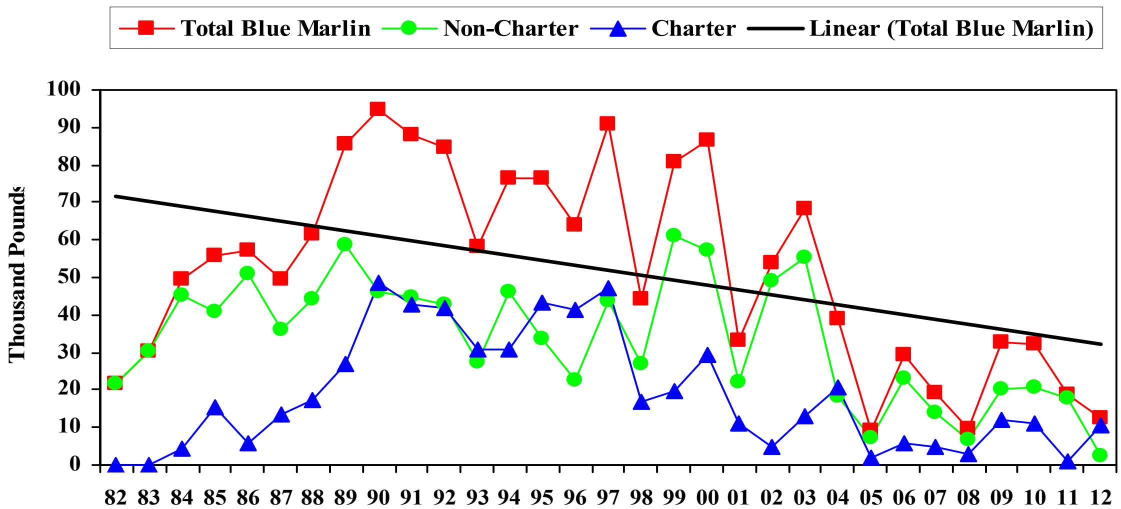
Figure 62. Guam annual estimated blue marlin landings: total landings, non-charter landings, charter landings



Interpretation: During the 1980s, non-charter boats accounted for the bulk of the blue marlin catch. In the early 1990s, the charter share of the marlin catch began to increase, peaking at 64% in 1996. The increases were due to an increase in charter boat activity and the active targeting of blue marlin by charter boats during the summer months. The decrease in charter landings after 1997 corresponded to the decrease in tourist charter trips. In 2012, total and non-charter blue marlin catch decreased by 33% and 88%, respectively. Charter landings of blue marlin increased in 2012 to 2009-2010 levels after very little harvest in 2011. Charter blue marlin landings accounted for 83% of the total blue marlin harvest. Total and non-charter blue marlin landings were below the 30 year average. The non-charter total is the lowest in the time series.

Source and Calculations: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files, expanded with the assistance of NMFS. Totals by species are summed across all fishing methods as described in Figure 56 through Figure 59.

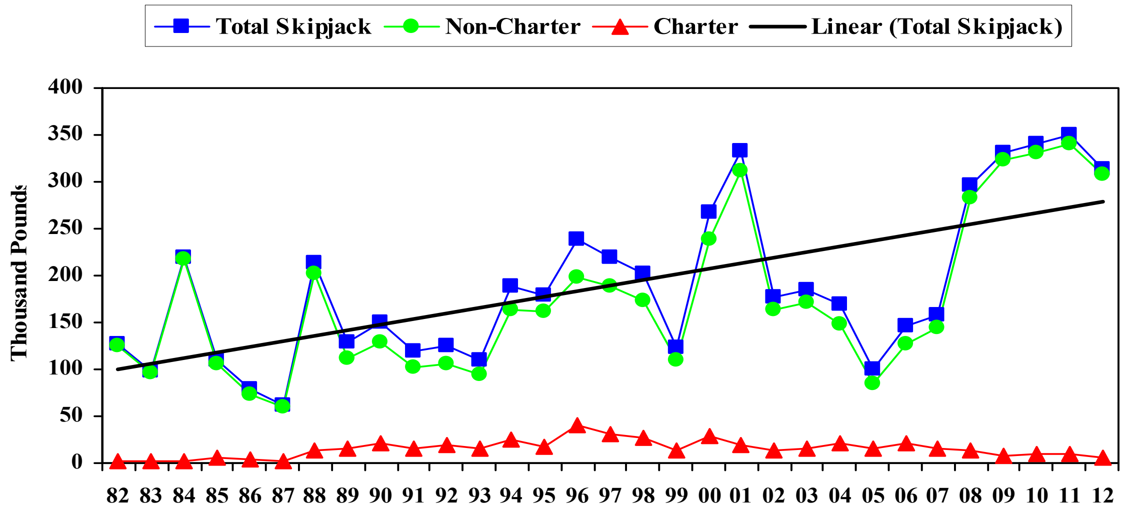
Figure 63. Guam annual estimated skipjack tuna landings: total, non-charter, and charter landings



Interpretation: Skipjack tuna catch has fluctuated over the reporting period, reaching a high in 2001 and again in 2011. The increasing catch in skipjack tuna since 2007 reflects an increase in small boats targeting this species, which are primarily crewed by Micronesian fishermen.

Total skipjack tuna, non-charter, and charter landings decreased in 2012 by 11%, 9.6%, and 46% respectively, after a peak in 2011. Total catch is well above the 30-year average.

Source and Calculations: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files, expanded with the assistance of NMFS. Totals by species are summed across all fishing methods as described in Figure 56 through Figure 59.

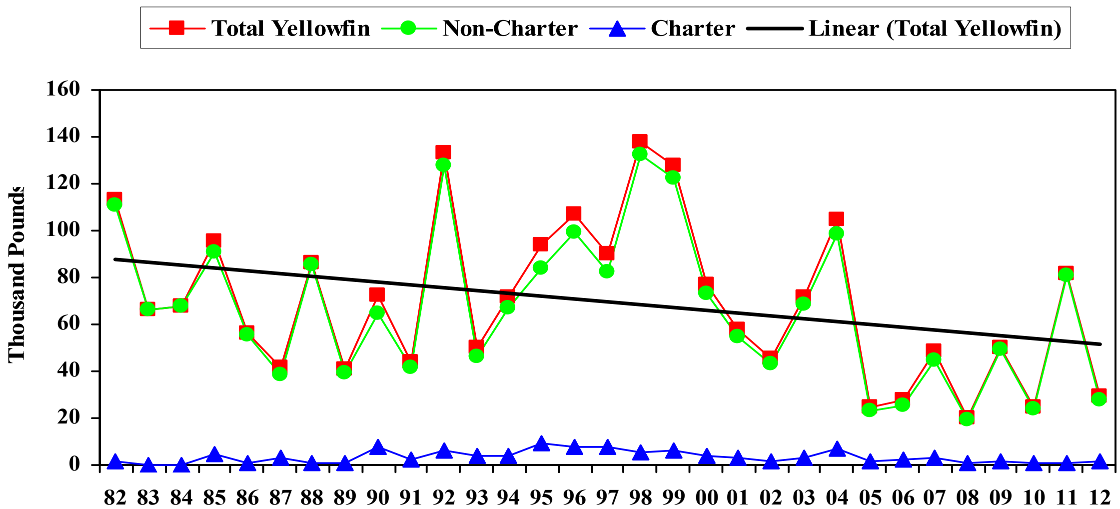
Figure 64. Guam annual estimated yellowfin tuna landings: total, non-charter, and charter landings



Interpretation: The overall yellowfin landings show wide fluctuations during the 30-year time series, although the total and non-charter estimated landings showed a significant decrease from 1998 to 2002 and have been on a steady decline over the 30-year time series. Charter landings of yellowfin tuna peaked in 1985, 1990, and 1995, and then showed a general decrease until 2002. Yellowfin tuna catch by charter boats was up significantly in 2012, with an increase of 69% over 2011. Total yellowfin tuna catch and non-charter catch decreased in 2012 by 64% and 66%, respectively. Non-charter boats harvested 94% of the total yearly catch of yellowfin. All categories are below their 30-year averages.

Source and Calculations: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files, expanded with the assistance of NMFS. Totals by species are summed across all fishing methods for all years except 1992-93 as described in Figure 56.

Table 61. Guam annual estimated yellowfin tuna landings: total, non-charter, and charter landings (pounds)

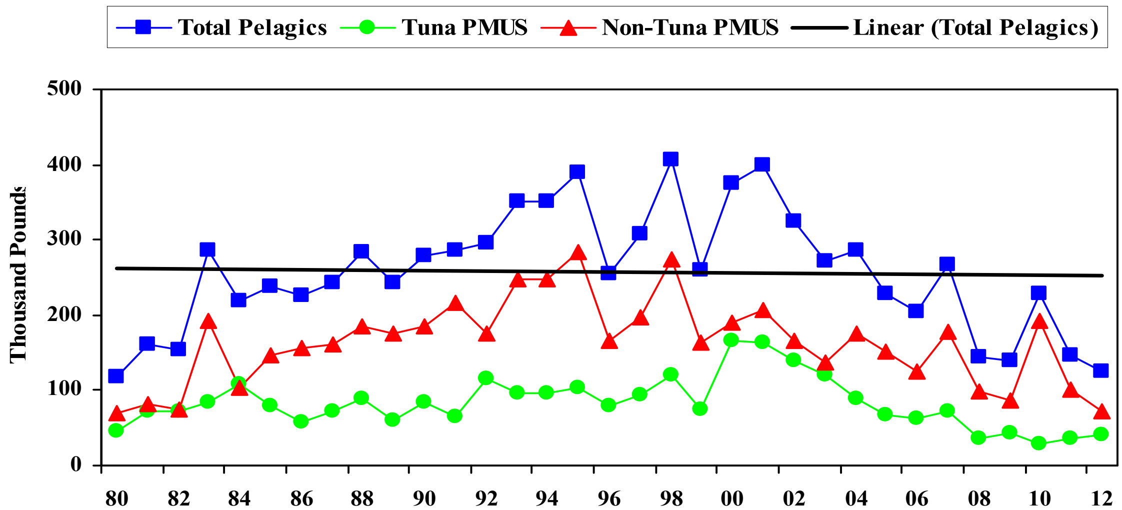
Figure 65. Guam annual estimated commercial landings: all pelagics, tuna PMUS, and non-tuna PMUS



Interpretation: Commercial pelagic fishery landings showed a general increase for the first 20 years in the 30-year time series, but the overall trend is slightly decreasing. In 2002, the estimated commercial landings decreased overall by 17%, with a 15% decrease for tuna landings and a 20% decrease for landings of other PMUS, possibly due to direct hits by two super typhoons resulting in boat damage, lack of tourist for the commercial charter boats, and unavailability of ice for fishermen. However, the total pelagic landings have steadily declined from 2002 with a couple upticks in 2007 and 2010. Total commercial catch in 2012 decreased 15% from 2011; tuna PMUS landings increased by 11% and non-tuna PMUS decreased by 28%. Total commercial catch is less than half of the 30 year average.

Source and Calculations: The WPACFIN-sponsored commercial landings system. Total commercial landings were estimated by summing the weight fields in the commercial landings database from the principle fish wholesalers on Guam, and then multiplying by an estimated percent coverage expansion factor. The annual expansion factor was subjectively created based on as much information as possible depending on the year, including: an analysis of the "disposition of catch" data available from the DAWR offshore creel survey; an evaluation of the fishermen in the fishery and their entry/exit patterns; general "dock-side" knowledge of the fishery and the status of the marketing conditions and structure; the overall number of records in the data base; and a certain measure of best guesses.

Table 62. Guam annual estimated commercial landings: all pelagics, tuna PMUS, and non-tuna PMUS

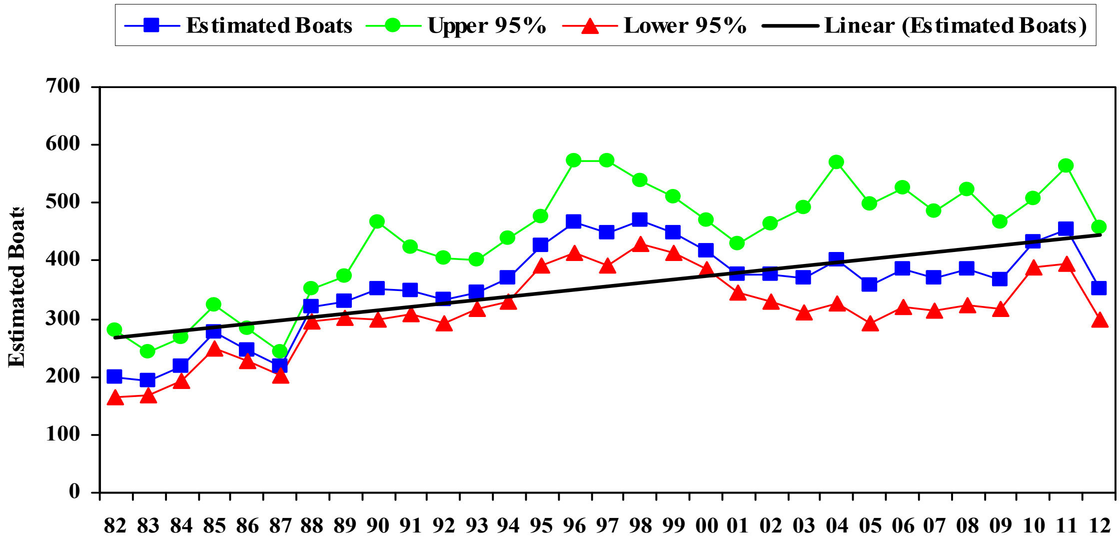
Figure 66. Guam estimated number of trolling vessels



Interpretation: Since 1982, the general trend on Guam has been an increase in the number of boats participating in the pelagic fishery, especially since the addition of two marinas to the offshore sampling program. There appears to be a general increase in the number of small boats participating in Guam's pelagic fishery, while the number of charter vessels has remained fairly constant for several years. While the number of vessels increased from 2010 to 2011 by 5% to 454, it decreased in 2012 to 351 vessels, or by 23%.

Source and Calculations: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files, expanded with the assistance of NMFS. Since only a fraction of the days of the year are sampled, it is not possible to know the exact number of boats participating in the fishery. The 2010 trolling boat log was converted and processed through a boat estimator model 1,000 times.

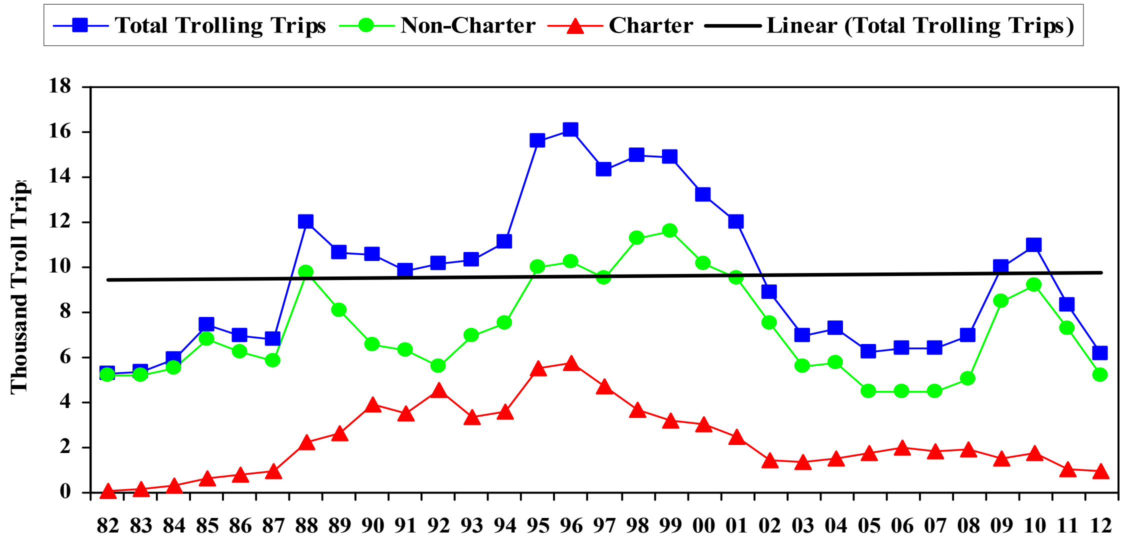
Figure 67. Guam estimated number of trolling trips



Interpretation: Non-charter and charter troll trips generally increased for the first 15 years of the 30-year time series. The number of troll trips began to decline in 1999 due to a number of factors including a continuing economic recession on the island, a decline in Asian visitors for charter boats, and an increase in cost to maintain, repair, and fuel boats for the average fishermen compared with fish caught for sale to make up for expenses. In 2012, the total number of troll trips returned to levels seen from 2003-2008, declining by 26% from 2011. The number of non-charter trips decreased by 29%, and the number of charter trips decreased by 8%. The decrease may be attributed to an increase in gas prices. Total trips are 36% below the 30 year average.

Source and Calculations: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files. The data expansion system is run on a calendar year's worth of survey data to produce catch and effort estimates for each fishing method surveyed. These plots are of the estimated number of trips for the trolling method as taken directly from creel survey expansion system printouts.

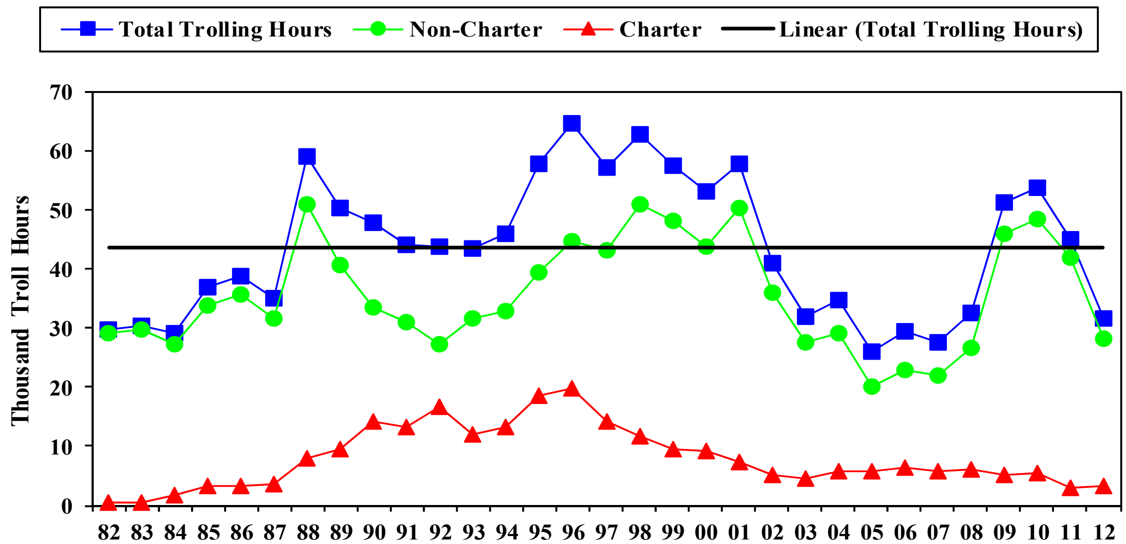
Figure 68. Guam estimated number of trolling hours



Interpretation: Trolling hours for non-charters and charters have generally increased over the first 15 years. Beginning in 1996, charter troll hours began to decrease. This corresponded to a downturn in Asian economies, which resulted in fewer charter trolling hours. After 2001, charter activity dropped off dramatically. Tourism was also down due to the 9/11 attacks, the SARS scare, and two typhoons striking Guam in 2002. From 2005 through 2010, the number of non-charter hours trolling generally increased, but dropped over the last two years, decreasing 33% from 2011 to 2012. Total trolling hours mirrored that decline. 2012 charter trolling hours increased slightly from 2011 by 10%. The decrease in hours trolling may be attributed higher gas prices and a high number of bad weather days in 2012. Total hours trolling were 27% below the 30-year average.

Source and Calculations: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files. The data expansion system is run on a calendar year's worth of survey data to produce catch and effort estimates for each fishing method surveyed. These plots are of the estimated boat hours spent fishing for the trolling method as taken directly from creel survey expansion system printouts.

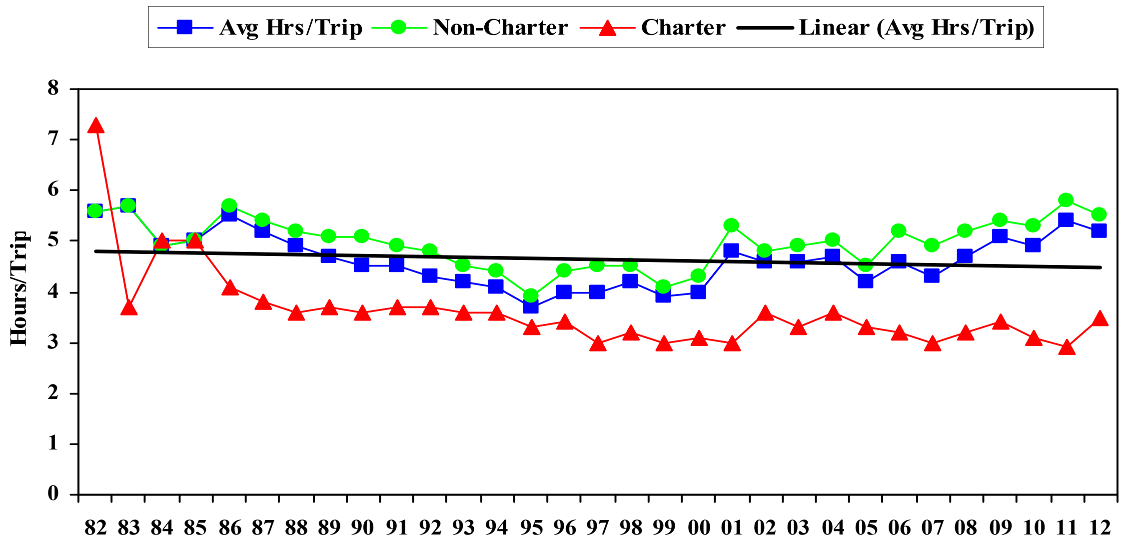
Figure 69. Guam estimated trip length (hours per trip)



Interpretation: The overall average trolling trip and non-charter average trolling trip decreased slightly in 2012 by 4% and 5% respectively. 2012 charter average hours per trip increased by 21%. The redeployment of fish aggregating devices (FADs) still provided charter boats and non-charter fishermen with a prescribed route for trolling activity, although many boats have been observed to be making longer trips to the banks located north and south of Guam. Overall trolling trip length appears to have remained fairly constant throughout the 30-year time series, and the 2012 overall average hours per trip is 13% higher than the 30 year average, as is the non-charter average hours per trip.

Source and Calculations: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files. The data expansion system is run on a calendar year's worth of survey data to produce catch and effort estimates for each fishing method surveyed. These plots are of the estimated boat hours spent fishing and number of trips for the trolling method, as taken directly from creel survey, expansion system printouts.

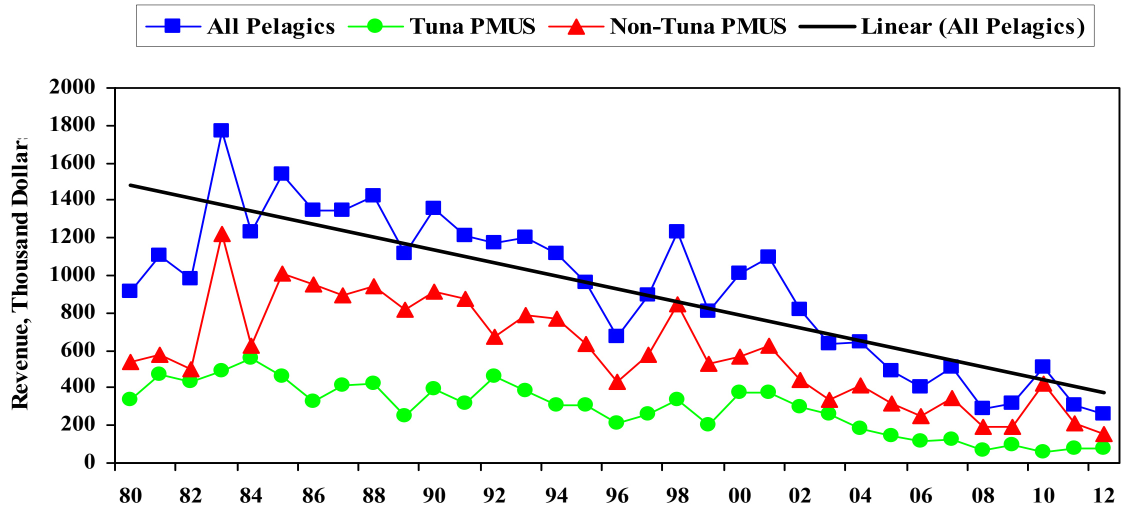
Figure 70. Guam estimated annual commercial revenues in inflation-adjusted dollars: all pelagics, tuna PMUS, and non-tuna PMUS



Interpretation: Commercial revenues have shown a gradual decrease since the early 1980's. A large drop occurring after 2002 can partly be attributed to two typhoons striking Guam, as well as a change in government policy (see introduction). This trend somewhat continued in 2012, with all three adjusted revenue categories well below the 31-year averages.

Source and Calculations: The WPACFIN-sponsored commercial landings system. Commercial revenues were estimated by summing the revenue fields in the commercial landings database from the principle fish wholesalers on Guam, and then multiplying by the same percent coverage expansion factor. Inflation-adjusted total revenue per trip is derived from the Guam Annual Consumer Price Index (CPI).

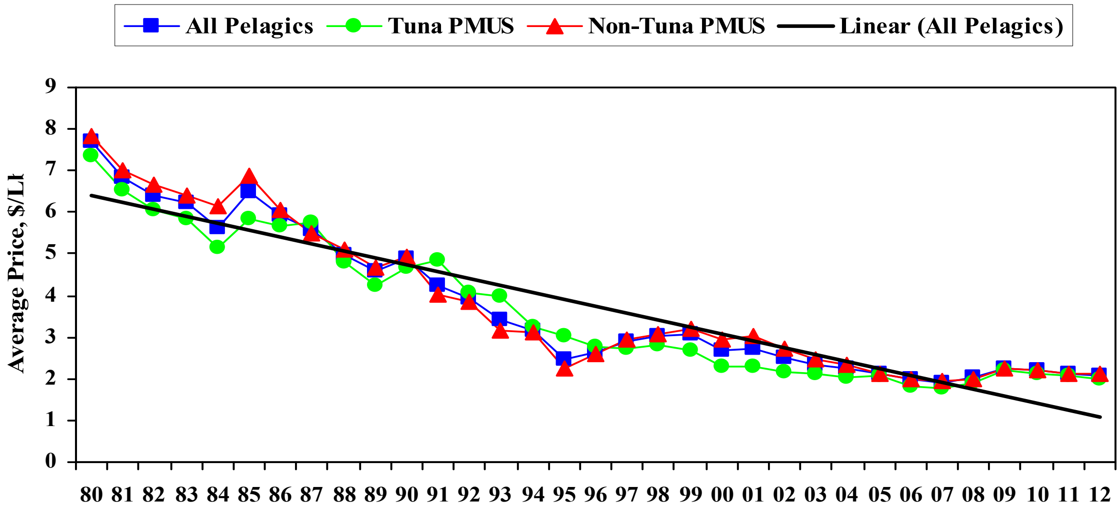
Figure 71. Guam annual estimated inflation-adjusted average price of pelagics ($/lb): all pelagics, tuna PMUS, and non-tuna PMUS



Interpretation: The inflation-adjusted price of tuna and other non-tuna PMUS has shown a steady decline since data on the pelagic fishery was first collected in 1980. In 2007, the trend started to change slightly. In 2012, prices were virtually unchanged, with the adjusted price for all pelagics decreasing 0.5%, 3.4% for tuna PMUS, and a 1% for non-tuna PMUS species. All three categories are well below their 30 year averages. Locally-caught pelagic fish continues to have to compete with cheaper pelagic fish caught by longliners. These are value-added products sold at several supermarkets and roadside vendors.

Source and Calculations: The WPACFIN-sponsored commercial landings system. The average price of the Tunas and other PMUS groups are calculated by dividing the total revenue for each by the sold weight. The inflation adjustment is made by using the Consumer Price Index (CPI) for Guam and establishing the current year figure as the base from which to calculate expansion factors for all previous years (e.g., divide the current year CPI by the CPI of any given year), and then multiplying that factor by the unadjusted average price for the given year.

Table 68. Guam annual estimated inflation-adjusted average price of pelagics ($/lb): all pelagics, tuna PMUS, and non-tuna PMUS

	All Pelagics		Tuna PMUS		Non-Tuna PMUS	
Year	**Unadjusted**	**Adjusted**	**Unadjusted**	**Adjusted**	**Unadjusted**	**Adjusted**

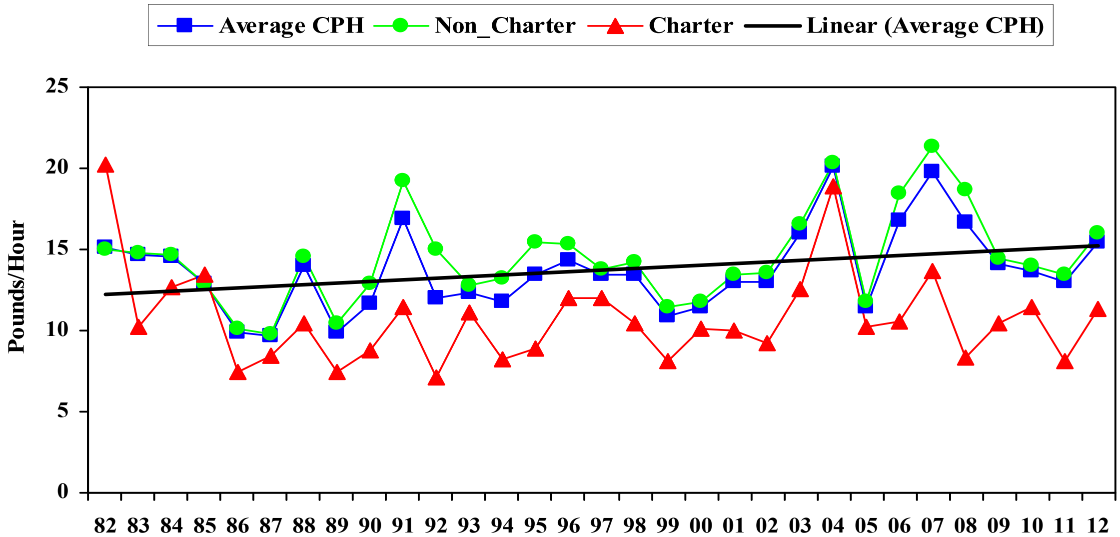
Figure 72. Guam trolling CPUE (lbs/hr)



Interpretation: The fluctuations in CPUE are probably due to variability in the year-to-year abundance and availability of the stocks. However, since it is not possible to allocate species-specific effort, effort used to target other species can also result in artificially high or low catch rates for a given species. This is especially true with charter boats targeting blue marlin during the summer months. In 2012, total overall, and non-charter catch rates increased 19.2% and 19.4%, respectively. Charter catch rates increased by 39.5%. Charter catch rates have generally been lower than catch rates of non-charter boats, probably due to their shorter fishing time and non-charter boats beginning earlier in the morning and ending as late as early evening.

Source and Calculations: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files. The data expansion system is run on a calendar year's worth of survey data to produce catch and effort estimates for each fishing method. This plot and table of catch per unit of effort (CPUE) are based on the total annual landings of all troll catch, divided by the total number of hours spent fishing (gear in use).

Table 69. Guam trolling CPUE (lbs/hr)

Year	Catch Rate	Non-Charter	Charter
1982	15.1	15.0	20.2
1983	14.7	14.8	10.2
1984	14.6	14.7	12.7

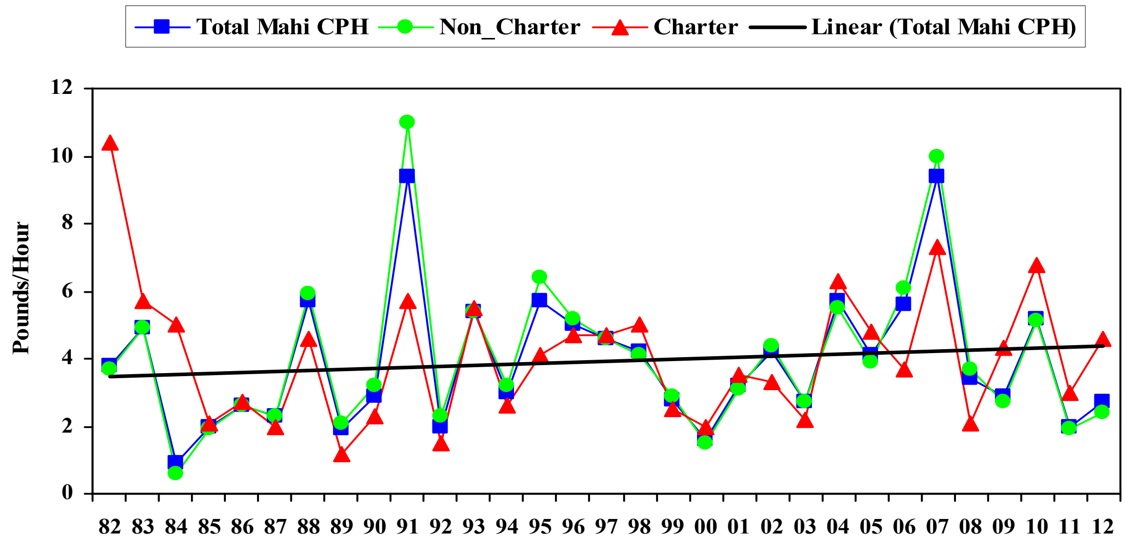
Standard Deviation	**2.5**	**2.8**	**2.9**

Figure 73. Guam trolling CPUE (lbs/hr): mahimahi



Interpretation: The wide fluctuations in mahimahi CPUEs are probably due to the high variability in the year-to-year abundance and availability of the stocks. It is not possible to allocate species-specific effort one particular species; effort used to target other species can result in artificially high or low catch rates for a given species. In 2012, the catch rate for total and non-charter mahimahi increased 35%, and 26%, respectively, while charter CPUE increased by 53%. Although CPUE increased in 2012, total mahimahi CPUE was 31% below the 31 year average.

Source and Calculations: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files. The data expansion system is run on a calendar year's worth of survey data to produce catch and effort estimates for each fishing method. This plot and table of catch per unit of effort (CPUE) are based on the total annual landings of mahimahi divided by the total number of hours spent fishing (gear in use).

Table 70. Guam boat-based creel trolling CPUE (lbs/hr): mahimahi

Year	Total Mahimahi	Non-Charter	Charter
1982	3.8	3.7	10.4

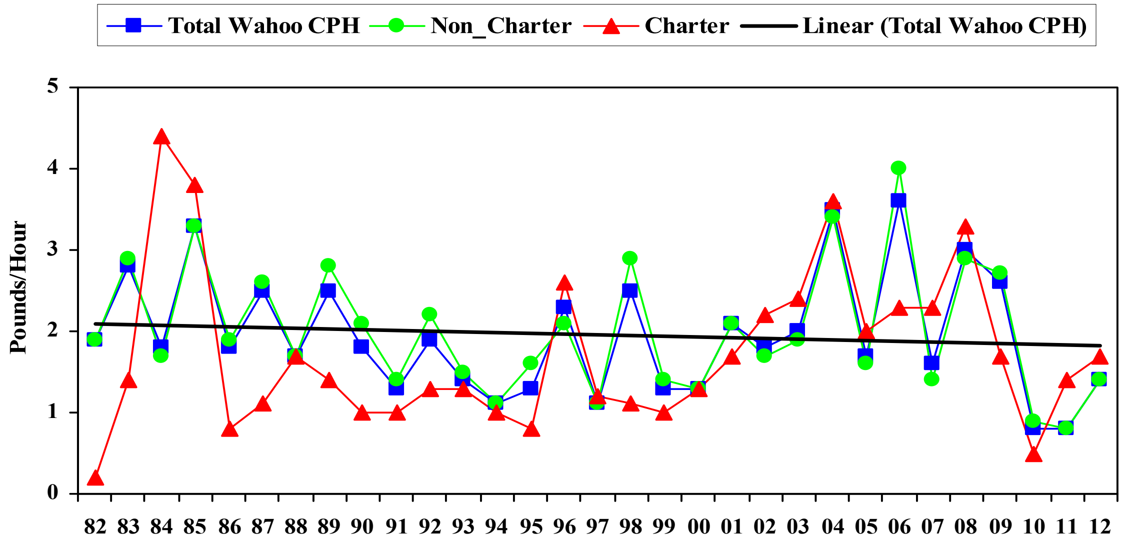
Figure 74. Guam trolling CPUE (lbs/hr): wahoo



Interpretation: The wide fluctuations in CPUEs are probably due to the high variability in the year-to-year abundance and availability of the stocks. The trend for the 30 year series has remained virtually unchanged. In 2012, all three categories increased. Total wahoo CPUE increased 75%, while non-charter CPUE increased by 75%. Charter CPUE increased by 21.4%. Total CPUE was 30% below the 30 year average.

Source and Calculations: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files. The data expansion system is run on a calendar year's worth of survey data to produce catch and effort estimates for each fishing method. This plot and table of catch per unit of effort (CPUE) are based on the total annual landings of wahoo divided by the total number of hours spent fishing (gear in use).

Table 71. Guam boat-based creel trolling CPUE (lbs/hr): wahoo

Year	Catch Rate	Non-Charter	Charter
1982	1.9	1.9	0.2
1983	2.8	2.9	1.4
1984	1.8	1.7	4.4

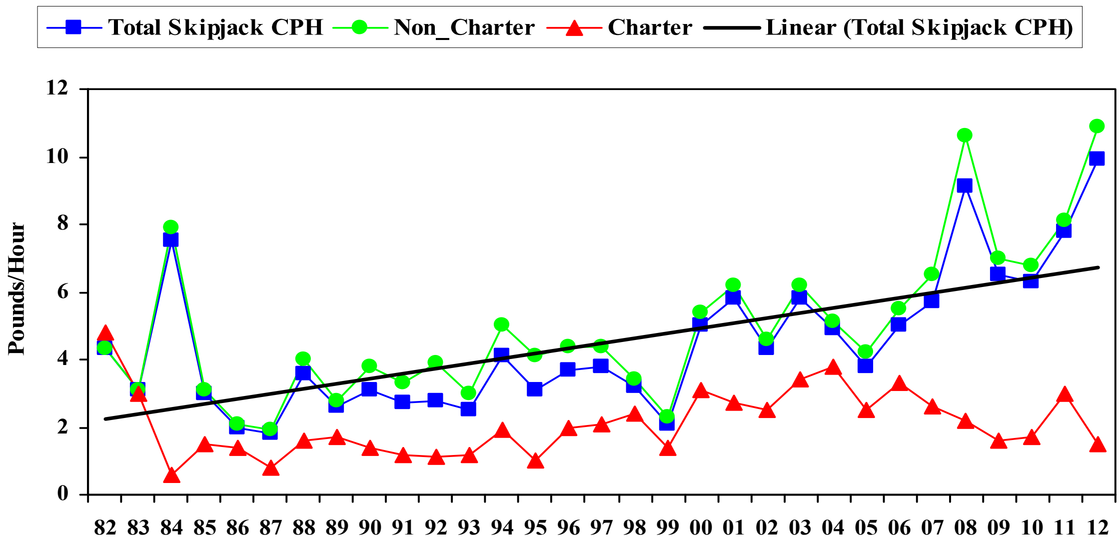
Figure 75. Guam trolling CPUE (lbs/hr): skipjack tuna



Interpretation: The wide fluctuations in CPUE for skipjack tuna are probably due to the high variability in the year-to-year abundance and availability of the stocks, although skipjack tuna is caught year round. However, it is not possible to allocate species-specific effort, since effort used to target other species can result in an artificially high or low catch rate for a given species. In 2012, the catch rates for total and non-charter increased by 26.9% and 34.6%, respectively. Charter rates decreased 50% in 2012. Total CPUE was 120% above the 30-year average.

Source and Calculations: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files, expanded with the assistance of NMFS. The data expansion system is run on a calendar year's worth of survey data to produce catch and effort estimates for each fishing method surveyed. This plot and table of catch per unit of effort (CPUE) are based on the total annual landings of skipjack divided by the total number of hours spent fishing (gear in use).

Table 72. Guam boat-based creel trolling CPUE (lbs/hr): skipjack tuna

Year	Total Skipjack	Non-Charter	Charter
1982	4.3	4.3	4.8
1983	3.1	3.1	3.0
1984	7.5	7.9	0.6
1985	3.0	3.1	1.5
1986	2.0	2.1	1.4

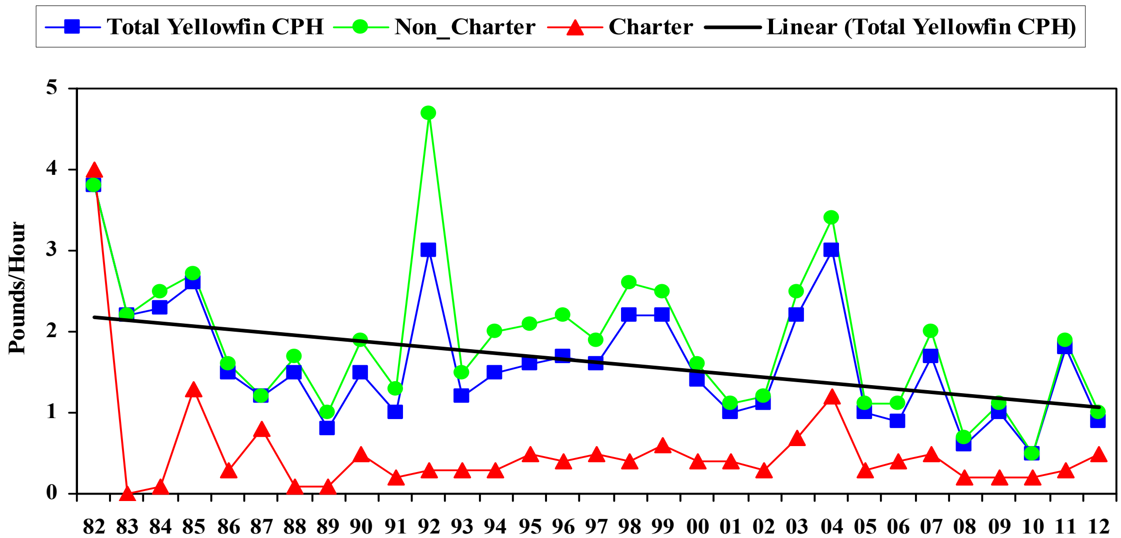
Figure 76. Guam trolling CPUE (lbs/hr): yellowfin tuna



Interpretation: The wide fluctuations in CPUE for yellowfin tunas are probably due to the high variability in the year-to-year abundance and availability of the stocks. It is not possible to allocate species-specific effort, since effort used to target other species can also result in an artificially high or low catch rate for a given species. In 2012, the yellowfin catch rates for total and non-charter catch decreased by 50% and 47% respectively. Charter CPUE increased 67%. All three categories are near their 30-year averages.

Source and Calculations: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files, expanded with the assistance of NMFS. The data expansion system is run on a calendar year's worth of survey data to produce catch and effort estimates for each fishing method surveyed. This plot and table of catch per unit of effort (CPUE) are based on the total annual landings of yellowfin divided by the total number of hours spent fishing (gear in use).

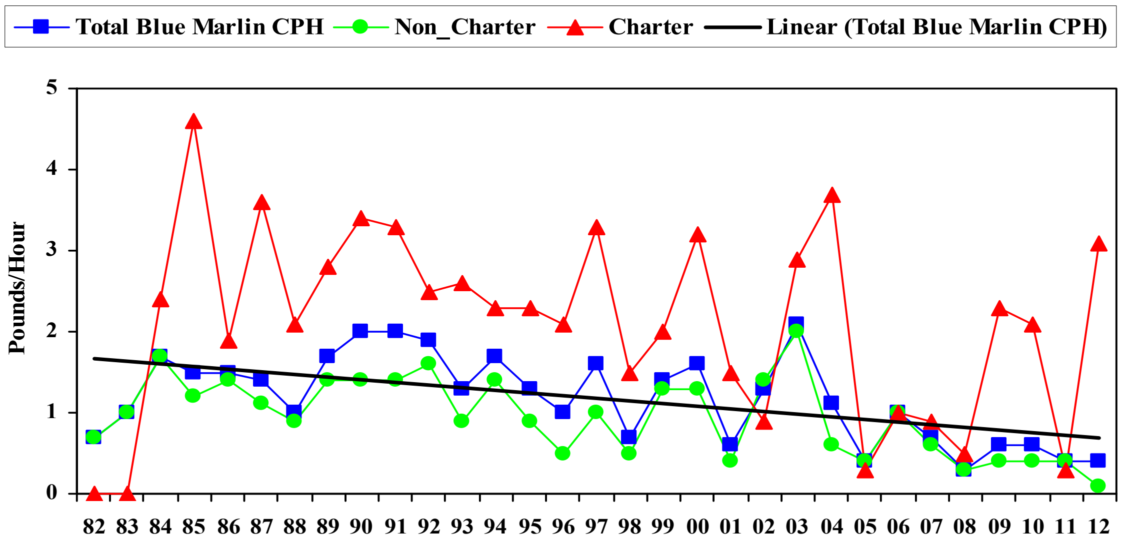
Figure 77. Guam trolling CPUE (lbs/hr): blue marlin



Interpretations: The wide fluctuations in CPUE are probably due to the high variability in the year-to-year abundance and availability of the stocks. Since it is not possible to allocate species-specific effort, effort used to target other species can also result in an artificially high or low catch rate for a given species. The 2012 blue marlin non charter CPUE declined 75% from 2011. Total CPUE was unchanged, while charter CPUE was up 1033%. Total catch CPUE is 67% below the 30 year average.

Source and Calculations: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files, expanded with the assistance of NMFS. The data expansion system is run on a calendar year's worth of survey data to produce catch and effort estimates for each fishing method surveyed. This plot and table of catch per unit of effort (CPUE) are based on the total annual landings of marlin divided by the total number of hours spent fishing (gear in use).

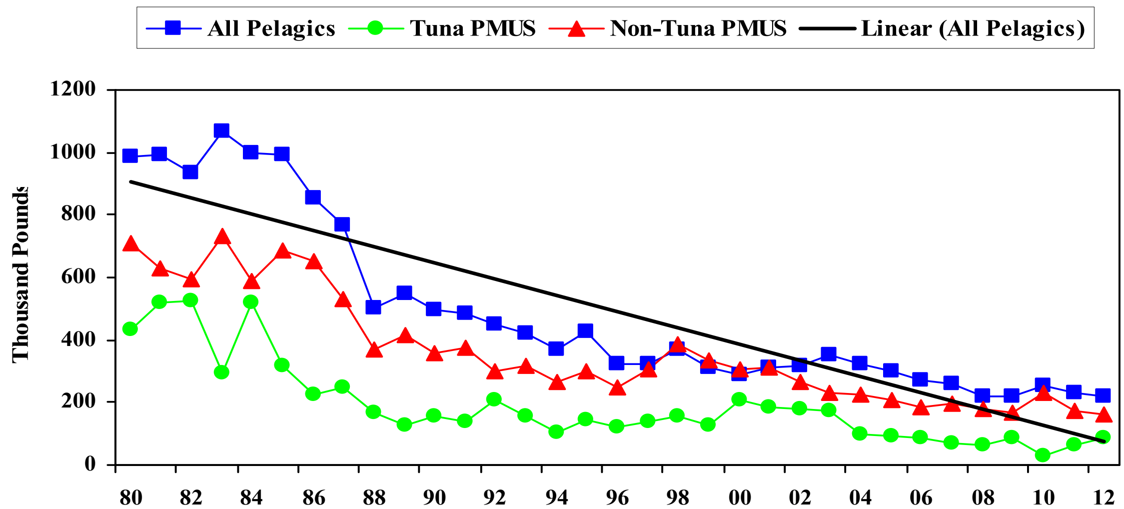
Figure 78. Guam annual inflation-adjusted revenue per trolling trip: all pelagics, tuna PMUS, and non-tuna PMUS



Interpretation: There has been a general decrease from 1980 in the adjusted revenues per trolling trip for all pelagics, tunas and other PMUS, although the revenue values have remained fairly constant for 10 years. In 2012, the adjusted revenue per trip decreased 5.3 % for all pelagics. Tuna PMUS revenues increased by 36.3%, and non-tuna PMUS decreased by 7%. Despite continual declines in revenues, trolling effort still occurs since most charter and non-charter trolling boats do not rely on selling fish caught as their primary source of income and a reliable market exists for members of the local fishermen's cooperative which provides additional income.

Source and Calculations: Data are from the WPacFIN-sponsored commercial landings system. The average revenue per trip was calculated by summing the revenue of all species sold then dividing by the number of trips, and summing the revenue of tunas and other PMUS sold, and then dividing each by the number of trips, respectively, for any trip, which landed PMUS. Adjusted revenue per trip was derived from the Guam Annual Consumer Price Index (CPI).

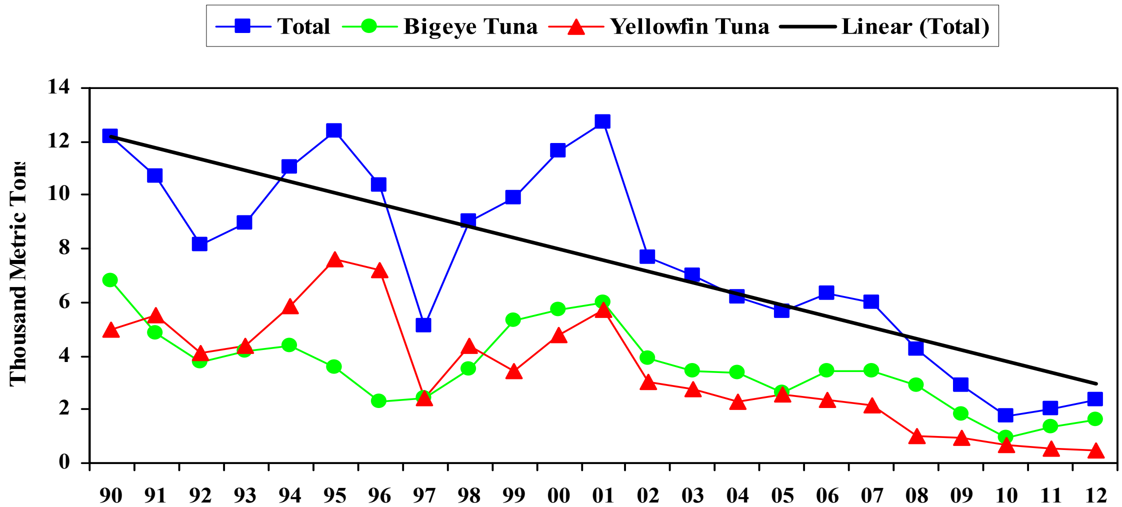
Figure 79. Guam foreign longline transshipment landings (mt) from vessels fishing outside the Guam EEZ



Interpretation: Annual landings from a primarily foreign longline fishing fleet have ranged from a low of 2,874 metric tons in 2009 to a high of 12,627 metric tons in 2001. These vessels fish primarily outside Guam's EEZ, but transship their catch through Guam. The dramatic drop observed in 1997 was due to a large number of foreign fishing boats leaving the western Pacific that year for several reasons, including availability of fish stocks. In 2012, total longline landings increased 16.1%, with bigeye landings increasing 21.9%, and yellowfin landings decreasing 7.5%. 2012 yellowfin totals were the lowest in the 23 year data set, and total catch was 69% below the 23 year average. The lower numbers may be due to a reduction in the number of agents reporting sales, and vessels relocating to other regions of the Pacific.

Source and Calculations: Data are from the Bureau of Statistics and Plans. Pre-1990 data was extracted directly from transshipment agents' files. Beginning in 1990, a mandatory data submission program was implemented.

Table 76. Guam foreign longline transshipment landings (mt)

*"percent bycatch" represents the number of pieces that were discarded compared to the total number of fish caught trolling. The bycatch information is from unexpanded data, taken only from actual interviews that reported bycatch.

Interpretation: Bycatch information was recorded beginning in 2000 as a requirement of the pelagic FMP. Historically, most fish landed are kept regardless of size and species. Bycatch for this fishery are sharks, shark-bitten pelagics, small pelagics, or other pelagic species. In 2010 and 2012, bycatch was not encountered by Fisheries staff when interviewing trollers.

Source and Calculations: The DAWR creel survey data for boat based methods. Bycatch is obtained directly from trolling interviews where bycatch was voluntarily reported. The number of bycatch reported is from unexpanded data.

D. Hawaii

Introduction

Hawaii's pelagic fisheries, which include the longline, main Hawaiian Island (MHI) troll and handline, offshore handline, and aku boat (pole and line) fisheries, are the state's largest and most valuable commercial fisheries. These pelagic fisheries landed an estimated 32 million pounds worth about $106 million (ex-vessel revenue) in 2012. The deep-set longline fishery was the largest of all commercial pelagic fisheries in Hawaii and represented 72% of the total commercial pelagic landings and 81% of the ex-vessel revenue. The MHI troll was the second largest fishery in Hawaii and accounted for 11% and 8% of the landings and revenue, respectively. The shallow-set longline, MHI handline, aku boat, offshore handline fisheries and other gear types made up the remainder.

Target species for Hawaii's pelagic fisheries are tunas and billfishes, but a variety of other pelagic species are also important to these fisheries. The largest component of the pelagic landings was tunas, which comprised 66% of the total in 2012. Bigeye tuna alone accounted for 66% of the tunas and 44% of all pelagic landings. Billfish landings made up 16% of the total landings in 2012. Swordfish was the largest of these at 61% of the billfish and 10% of the total landings. Landings of other pelagic management unit species (PMUS) represented 18% of the total landings in 2012 with mahimahi being the largest component at 34% of the other PMUS and 6% of the total landings.

Data Sources and Calculation Procedures

This report contains the most recently available information on Hawaii's commercial pelagic fisheries, as compiled from three data sources: The State of Hawaii's Division of Aquatic Resources (HDAR) Commercial Fishing Report data (Fishing Report), HDAR Commercial Marine Dealer (Dealer) data, and the National Oceanic and Atmospheric Administration (NOAA) Fisheries, Pacific Islands Fisheries Science Center's (PIFSC) longline logbook data. The data sources and estimation procedures are described below.

The Hawaii-based Longline Fishery: The federal longline logbook system was implemented in December 1990 and served as the source of the data used to determine fish catches. The number of "Fish Kept" from the longline logbook data was multiplied by the average weight per fish from HDAR Dealer data to estimate total kept catch. The revenue in this report originates from the Dealer and is a sum of the "Amount Paid" for the "Fish Bought". To satisfy confidentiality standards as well as comply with Regional Fisheries Management Organization (RFMO) or International data and reporting standards, longline vessels landings their catch in California were also included in the following data summaries. However, longline size summaries, revenue and average prices are only for longline vessels landing their catch in Hawaii.

MHI Troll Fishery: Catch and effort by the MHI troll fishery was defined as using a combination of pelagic species, gear and area codes from the HDAR Fishing Report data. The codes for the MHI troll fishery includes summaries of PMUS caught by Miscellaneous Trolling Methods (HDAR gear code 6), Lure Trolling (61), Bait Trolling (62), Stick Trolling (63), Casting, Light Tackle, Spinners or Whipping (10) and Hybrid Methods (97) in HDAR statistical areas 100 through 642. These are areas that begin from the shoreline out to 20 minute squares around the islands of Hawaii, Maui, Kahoolawe, Lanai, Mokolai, Oahu, Kauai and Niihau.

MHI Handline Fishery: The MHI handline fishery includes PMUS caught by Deep Sea or Bottom Handline Methods (HDAR gear code 3), Inshore Handline or Cowrie Shell (Tako) Methods (4), Ika_Shibi (8), Palu-Ahi, Drop Stone or Make Dog Methods (9), Drifting Pelagic Handline Methods (35) and Floatline Methods (91) in HDAR statistical areas 100 to 642 except areas 175, 176, and 181.

Offshore Handline Fishery: The offshore handline fishery includes PMUS caught by Ika-Shibi (HDAR gear code 8), Palu-Ahi, Drop Stone or Make Dog Methods (9), Drifting Pelagic Handline Methods (35), Miscellaneous Trolling Methods (6), Lure Trolling (61), and Hybrid Methods (97) in Areas 15217 (NOAA Weather Buoy W4), 15717 (NOAA Weather Buoy W2), 15815, 15818 (Cross Seamount) , 16019 (NOAA Weather Buoy W3), 16223 (NOAA Weather Buoy W1), 175, 176, 181, 804, 807, 816, 817, 825, 839, 842, 892, 893, 894, 898, 900, 901, 15416, 15417, 15423, 15523, 15718, 15918, 15819, and 16221. This fishery also includes pelagic species caught by Deep Sea or Bottom Handline Methods (3) in Area 16223.

Other Gear: This category represents pelagic species caught by other methods or in areas other than those methods mentioned above. Catch and revenue from this category is primarily composed of PMUS caught by the aku boat fishery, fishers trolling in areas outside of the MHI (the distant water albacore troll fishery) or PMUS caught close to shore by diving, spearfishing, squidding, or netting inside of the MHI.

Calculations: Calculating catch by the MHI troll, MHI handline, offshore handline, and other gear involved processing of two data sets: the HDAR Fishing Report data collected and submitted by the aforementioned fishers, and HDAR Dealer data collected and submitted by seafood dealers. “Pounds Landed” from HDAR Fishing Report data was summed by species for each of the above fisheries. Total “Pounds Landed” for each species was then calculated by summing the catch of that particular species for the MHI troll, MHI handline, offshore handline fisheries and other gear category. The percent catch of each species by fishery was also calculated and later used in conjunction with the HDAR Dealer data.

Catch in the HDAR Dealer data, referred to as “Pounds Bought”, by each fishery was not clearly differentiated; however, “Pounds Bought” by the longline and aku boat fisheries were identified by CML numbers and/or vessel names and kept separate from the “non-longline & non-aku boat” Dealer data. The remaining “non-longline and non-aku” boat “Pounds Bought” was presumed to be from the MHI troll, MHI handline, offshore handline fisheries or other gear category. “Pounds Bought” from this data was summed on a species specific basis with fishery specific landings of each particular species allocated based on the percent catch by fishery calculated from the HDAR Dealer data. The fishery specific HDAR Dealer data allocation was then compared to the “Pounds Landed” from the HDAR Fishing Report total. The greater value of “Pounds Bought” from the HDAR Dealer data or the “Pounds Landed” from the HDAR Fishing Report catch data was used as the catch. This process was repeated on a monthly basis.

This module was prepared by Russell Ito of the PIFSC. Summaries for the longline fishery that originate from NOAA Fisheries longline logbook data were provided by Karen Sender of the PIFSC. NOAA Fisheries logbook data that were integrated with corresponding HDAR Dealer data was provided by Dios Gonzales and Grace Kagami from the PIFSC. HDAR Commercial Fish Catch and Dealer data used calculate the MHI troll, MHI handline, offshore handline, and other gear landings were compiled by Karen Brousseau and Ashley Tomita from JIMAR. Information on HDAR CMLs was provided by Reginald Kokubun of HDAR.

Plan Team Recommendations

There were no recommendations by the Pelagics Plan Team for 2012.

Table 79. Number of Hawaii licenses per fishing method in 2011-2012

Primary Fishing Method	Number of licensees 2011	2012
Trolling	1,295	1,221
Longline	626	752
Ika Shibi & Palu Ahi	211	241
Aku Boat (Pole and Line)	17	16
Total Pelagic	2,149	2,230
Total All Methods	3,762	3,841

Interpretation: A total of 3,841 fishermen were licensed in 2012, including 2,230 (58%) who indicated that their primary fishing method and gear was intended to catch pelagic fish. Most licenses that indicated pelagic fishing as their primary method were issued to trollers (55%) and longline fishermen (34%). The remainder was issued to ika shibi and palu ahi (handline) (11%) and aku boat fishers (1%).

Sources and calculations: Any fisherman who takes marine species for commercial purposes is required by the State of Hawaii, Division of Aquatic Resources (HDAR) to have a Commercial Marine License (CML) and submit a monthly catch report. An exception to this rule is that should a fishing trip occur on a boat, only one person per vessel is required to submit a catch report. This person is usually, but not necessarily, the captain. Crew members do not ordinarily submit catch reports. HDAR asks fishermen to identify their primary fishing gear or method on the CML at time of licensing. This does not preclude fishermen from using other gears or methods.

Table 80. Hawaii commercial pelagic landings, revenue, and average price by species, 2011-2012

	2011			2012		
Species	Pounds landed (x 1000)	Ex-vessel revenue ($1000)	Average price ($/lb)	Pounds landed (x 1000)	Ex-vessel revenue ($1000)	Average price ($/lb)
Tuna PMUS

Yellowfin tuna	3,877	$10,063	$2.93	4,098	$13,173	$3.67
Other tunas	23	$57	$3.06	67	$240	$3.81
Tuna PMUS subtotal	**20,235**	**$67,646**	**$3.63**	**21,104**	**$82,258**	**$4.17**
Billfish PMUS						
Swordfish	3,569	$6,829	$2.57	3,094	$6,699	$2.81
Blue marlin	1,247	$1,266	$1.36	951	$1,449	$1.83
Spearfish (hebi)	543	$559	$1.25	386	$697	$2.17
Striped marlin	835	$1,147	$1.13	648	$1,411	$1.84
Other marlins	40	$27	$1.46	30	$40	$3.63
Billfish PMUS subtotal	**6,234**	**$9,828**	**$1.96**	**5,109**	**$10,295**	**$2.44**
Other PMUS						
Mahimahi	1,628	$4,427	$3.06	2,007	$5,276	$3.04
Ono (wahoo)	675	$1,821	$3.23	809	$2,262	$3.55
Opah (moonfish)	1,622	$2,918	$1.82	1,593	$3,163	$2.04
Oilfish	589	$889	$1.38	563	$852	$1.41
Pomfrets (monchong)	422	$1,472	$3.39	710	$2,088	$2.87
PMUS Sharks	190	$117	$1.05	181	$129	$1.28
Other PMUS subtotal	**5,126**	**$11,643**	**$2.42**	**5,863**	**$13,770**	**$2.57**
Other pelagics	**51**	**$43**	**$2.93**	**26**	**$38**	**$1.79**
Total pelagics	**31,646**	**$89,160**	**$3.13**	**32,102**	**$106,362**	**$3.62**

Interpretation: The total commercial pelagic landings in 2012 were 32.1 million pounds, up 3% from 2011. Tunas represented 66% of the total landings. Bigeye tuna was the largest component of the pelagic landings (44%) followed by yellowfin tuna (13%) and swordfish (10%).

Total Hawaii commercial ex-vessel revenue exceeded $100 million in 2012, a first time for these fisheries. This represented an increase of 19% in revenue from the previous year. Tunas comprised 77% of total revenue. Bigeye tuna alone accounted for 60% of the total revenue at $64 million. Yellowfin tuna revenue increased 31% to $13 million. Billfish revenue ($10.3 million) was close to last year's revenue. Swordfish was the third highest contributor to total revenue at $6.7 million. Revenue of other PMUS increased 18% in 2012. The average price for pelagic fish was strong in 2012 increasing by 16%. Average prices for all species groups rose in 2012.

Source and Calculations: NOAA Fisheries longline logbook and HDAR Dealer data were used to produce longline landings, revenue, and average price estimates. The Main Hawaiian Islands (MHI) troll, MHI handline, offshore handline, and other gear landings, revenue, and average price estimates were produced from HDAR Commercial Fish Catch and Dealer data.

Tuna MUS included albacore, bigeye tuna, bluefin tuna, skipjack tuna, yellowfin tuna and other tuna species such as kawakawa, keokeo. Billifsh MUS are composed on swordfish, blue marlin, striped marlin, spearfish, sailfish, black marlin and unclassified marlins. Mahimahi, monchong, moonfish, oilfish, and ono made up the other PMUS. The shark MUS were blue shark, mako shark, thresher shark, and white-tipped sharks. "Other pelagics" includes non-PMUS fish species.

The revenue for the current year is an unadjusted value while the revenue for the previous year is adjusted by the CPI. The average price is the total revenue divided by the pounds sold for each species where pounds sold is equal to or less than the total catch for each species.

Table 81. Hawaii-based deep-set and shallow-set longline landings, ex-vessel value, and average price by species 2011-2012

<u>Interpretation</u>: Deep-set longline landings was slightly higher in 2012, but ex-vessel revenue and average price for the deep-set longline fishery increased by 19% and 16%, respectively. Although the average price for the shallow-set longline fishery increased in 2012, its landings and ex-vessel revenue decreased. Bigeye tuna is the largest component of the landings and the most valuable species for the deep-set longline fishery while swordfish was the most important species in terms of landings and revenue for the shallow-set longline fishery.

<u>Source and calculations:</u>
The NOAA Fisheries longline logbook data (number of fish kept) was used in conjunction with the HDAR Commercial Marine Dealer data (average pounds) to calculate pounds kept or landings. The longline ex-vessel revenue was calculated by summing longline records in the HDAR Commercial Marine Dealer data for each species. The HDAR Dealer data was used to calculate average price by dividing the "Amount Paid" for longline fish sales by the "Pounds Bought". Ex-vessel revenue and average price was adjusted for inflation by dividing the current year Honolulu CPI (H-CPI) by the previous year H-CPI then multiplying the nominal revenue for that respective year.

Table 82. Hawaii commercial pelagic landings, revenue, and average price by fishery, 2011-2012

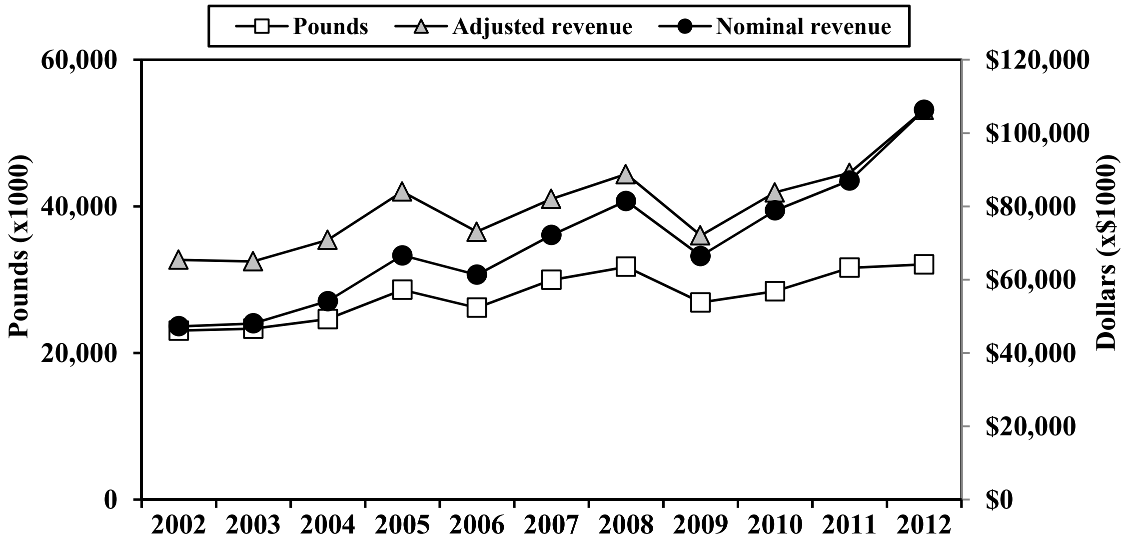
	2011			2012		
Fishery	Pounds landed (x1000)	Ex-vessel revenue ($1000)	Average price ($/lb)	Pounds landed (x1000)	Ex-vessel revenue ($1000)	Average price ($/lb)
Deep-set longline	22,796	$72,871	$3.29	22,975	$86,520	$3.82
Shallow-set longline	3,500	$6,234	$2.49	2,814	$5,814	$2.84
MHI trolling	2,966	$5,906	$2.92	3,690	$8,594	$3.29
MHI handline	1,129	$2,184	$2.54	1,602	$3,361	$2.54
Offshore handline	610	$854	$2.41	562	$1,094	$2.95
Other gear	645	$1,112	$2.01	459	$979	$2.81
Total	**31,646**	**$89,160**	**$3.13**	**32,102**	**$106,362**	**$3.62**

Interpretation: The deep-set longline fishery is the largest commercial fishery in Hawaii. The deep-set longline landings and revenue were 23.0 million pounds and $86.50 million, respectively, in 2012. Landings by this fishery increased by only 179,000 pounds but revenue rose $13.6 million in 2012. The average price for the deep-set longline fishery was the difference increasing by 16% in 2012. The MHI troll fishery was the second largest commercial fishery. It produced 3.7 million pounds worth $8.6 million; an increase of 25% and 46%, respectively, from the previous year. The MHI handline fishery produced 1.6 million pounds of pelagic fish worth $3.4 million while the offshore handline fishery landed 562,000 pounds worth $1.1 million in 2012.

Source and calculations: Number of fish from the NOAA Fisheries longline logbook data and average weight of fish from the HDAR Commercial Marine Dealer (Dealer) data were used to calculate longline landings. The ex-vessel revenue was the sum of "Amount Paid" from the HDAR Dealer data. The average price was calculated by dividing the total "Amount Paid" by the "Pounds Bought" from the Dealer data.

The landings and revenue is the sum of the all pelagic species for each fishery. The revenue for 2011 is inflation-adjusted by the Honolulu CPI. The average price was calculated from the HDAR Commercial Marine Dealer data by dividing the "Amount Paid" by the "Pounds Bought" for each fishery.

Figure 80. Hawaii total commercial landings and revenue, 2002-2012



Interpretation: Commercial landings and revenue in 2012 reached record highs of 32.1 million pounds worth an estimated $106.4 million. The trend for both landings and inflation-adjusted revenue were increasing. Gear and species specific changes over the 11-year period are explained in greater detail in the following figures and tables.

Source and calculations: The pounds and nominal revenue values are obtained by adding the landings and revenue values for all species and all fisheries for each year. The inflation-adjusted revenue for each year is calculated by multiplying the nominal value by the Honolulu CPI for the current year and then dividing by the Honolulu CPI for that year.

Year	Pounds (1000)	Nominal revenue ($1000)	Adjusted revenue ($1000)	Honolulu CPI
2002	23,061	$47,316	$65,476	180.3
2003	23,330	$48,069	$65,004	184.5
2004	24,622	$54,147	$70,880	190.6
2005	28,631	$66,651	$84,073	197.8
2006	26,178	$61,349	$73,098	209.4
2007	29,980	$72,196	$82,064	219.5

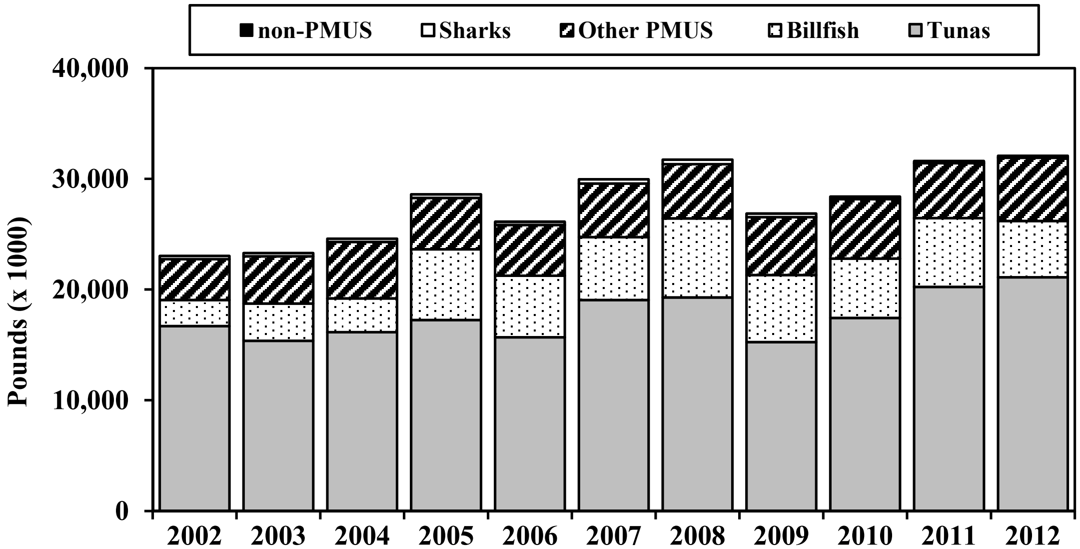
Average	**27,876.1**	**70,003.2**	**80,080.4**	
SD	**3,327.9**	**17,818.3**	**12,333.8**	

Figure 81. Hawaii commercial tuna, billfish, shark, and other PMUS landings, 2002-2012



Interpretation: Hawaii's pelagic landings reached a record 32.1 million pounds in 2012. Tunas were the largest group followed by other PMUS and billfish. In general, the trends for tuna, billfish and other PMUS were increasing. Sharks and non-PMUS landings were relatively small.

Source and calculations: Pelagic landings were calculated from NOAA Fisheries longline logbook, HDAR Commercial Fish Catch and Marine Dealer data. The landings values are obtained by adding the landing values for species in the pelagic species groups defined below for the longline and non-longline fisheries for each year. The PMUS in each group included:

Tunas:	Albacore, Bigeye tuna, Bluefin tuna, Kawakawa, Skipjack tuna, Unclassified tuna, Yellowfin tuna
Billfishes:	Blue marlin, Black marlin, Sailfish, Spearfish, Striped marlin, Swordfish, Unclassified billfish
Other PMUS:	Mahimahi, Moonfish, Oilfish, Pomfret, Wahoo
Sharks:	Blue shark, Mako shark, Thresher shark, Oceanic white-tip shark
Non-PMUS:	Barracuda, Beltfish, Flying fish, Frigate mackeral, Stingray, Sunfish, Hammerhead shark, Tiger shark, Unclassified sharks

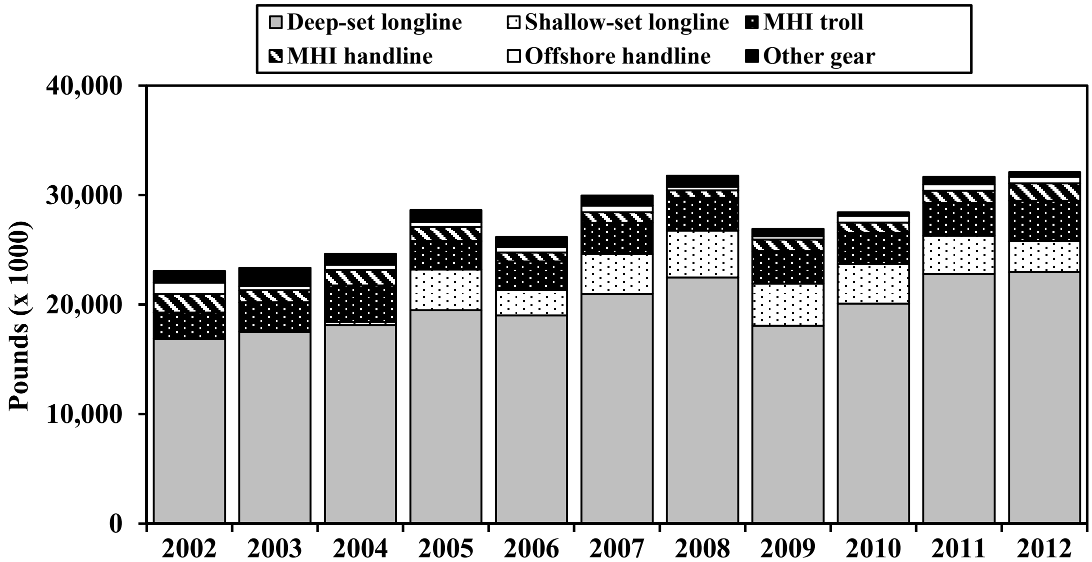
Figure 82. Hawaii total commercial pelagic landings by gear type 2002-2012



Interpretation: Hawaii commercial pelagic landings were dominated by deep-set longline fishery. Total landings increased to a record level largely due to higher landings by this fishery and higher landings by the shallow-set longline fishery. MHI troll was typically the third largest fishery, but became the second largest fishery in 2012. Landings by the MHI handline and offshore fisheries were the next two largest fisheries in Hawaii. Landings by the offshore handline and other gear accounted for 1 million pounds in 2012.

Source and calculations: Pelagic landings were calculated from NOAA Fisheries longline logbook, HDAR Commercial Fish Catch and Marine Dealer data. The landing estimates were calculated by adding the landings values of all species of each fishery. The total column includes the five major pelagic fisheries and contributions from the other gear category. The other gear category includes landings from the aku boat fishery to maintain confidentiality standard of the fishery statistics.

	Hawaii pelagic total landings (1000 pounds)						
Year	Deep-set longline	Shallow-set longline	MHI troll	MHI handline	Offshore handline	Other gear	Total
2002	16,868	0	2,387	1,693	1,058	1055	23,061

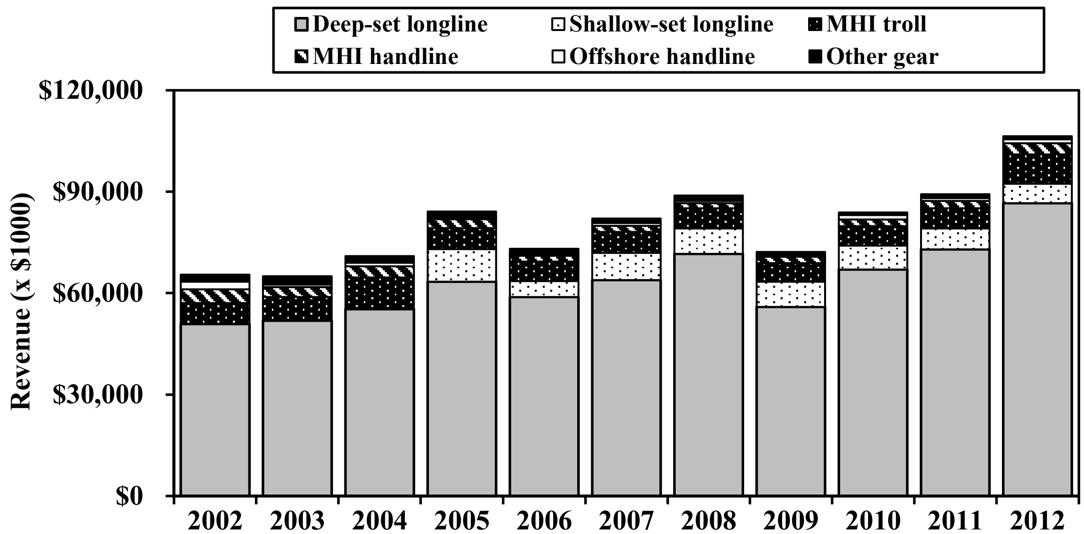
Figure 83. Total commercial pelagic ex-vessel revenue by gear type 2002-2012



<u>Interpretation:</u> Ex-vessel revenue from Hawaii's pelagic fisheries has been trending upward reaching a record $106 million in 2012, up 19% from the previous year. The highest grossing fishery in Hawaii was the deep-set longline, which accounted for 81% of the total revenue, or $86.5 million, in 2012. The next three largest revenue generating fisheries were the MHI troll, shallow-set longline, and MHI handline fisheries. MHI troll revenue decreased gradually from its peak of $8.9 million in 2004, but increased in 2012. Shallow-set longline revenue increased dramatically after it reopened in 2004 but decreased gradually to $5.8 million in 2012. MHI handline revenue has been increasing from its low of $1.5 million in 2008 to $3.4 million in 2012. The offshore handline fishery and other gear category (which also includes aku boat revenue) generated $2.1 million in 2012.

<u>Source and Calculations:</u> The HDAR Commercial Marine Dealer data was used in conjunction with the NOAA Fisheries logbook and the HDAR Fish Report data to calculated ex-vessel revenue. Ex-vessel revenue values were obtained by adding the revenue for all pelagic species of each fishery for each year. Ex-vessel revenue was then adjusted for inflation using the Honolulu Consumer Price Index (CPI).

	Hawaii pelagic total revenue ($1000)							
Year	Deep-set longline	Shallow-set longline	MHI troll	MHI handline	Offshore handline	Other gear	Total	Honolulu CPI
2002	$50,849	$0	$6,224	$4,027	$2,278	$2,098	$65,476	180.3
2003	$51,837	$0	$7,044	$2,855	$776	$2,492	$65,004	184.5
2004	$55,264	$392	$8,907	$3,286	$1,114	$1,918	$70,880	190.6

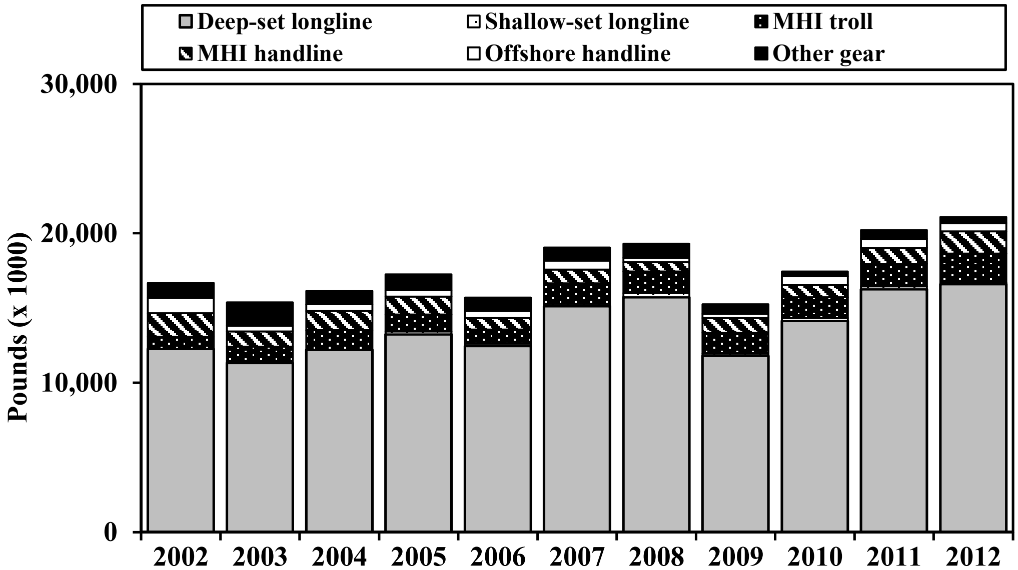
Figure 84. Hawaii commercial tuna landings by gear type, 2002-2012



Interpretation: The deep-set longline fishery was the largest single contributor to the tuna landings. It accounted for 78% of the tuna landings during 2002-2012. The MHI troll fishery was the second largest fishery, followed by the MHI handline and offshore handline fisheries. Tuna landings by other gear also included the aku boat fishery, which was responsible for a large part of the decline in this category.

Source and calculations: Tuna landings by gear types were summarized for the longline, MHI troll, MHI handline, offshore handline, aku boat fisheries, and other gear. The tuna landing statistics for the longline fishery were derived from NOAA Fisheries longline logbook and HDAR Commercial Marine Dealer data while landing estimates for the MHI troll, MHI handline, offshore handline, fisheries and other gear category originate from HDAR Commercial Fish Catch and Marine Dealer data.

	Hawaii tuna landings by gear type (1000 pounds)

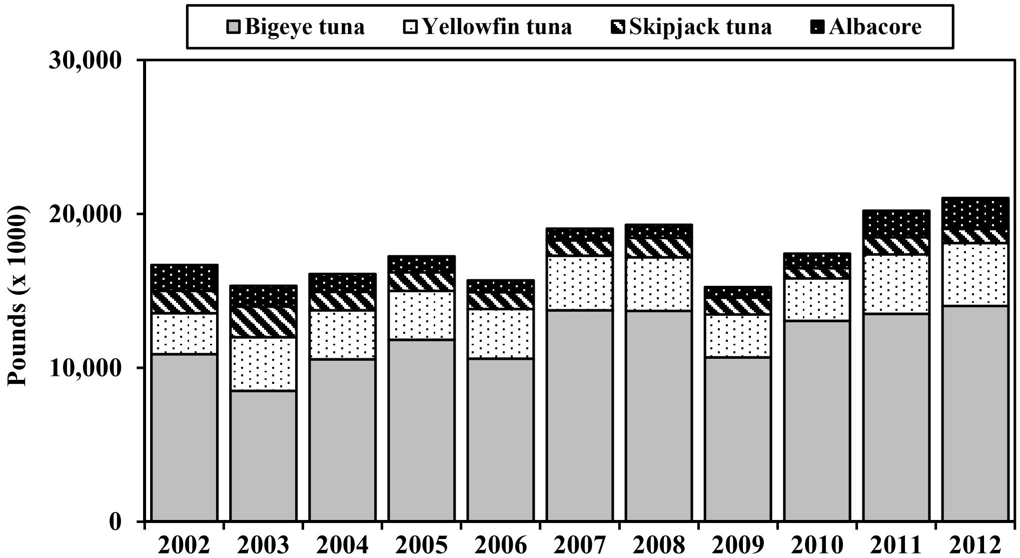
Figure 85. Species composition of the tuna landings, 2002-2012



Interpretation: Bigeye tuna was the largest component of the tuna landings and reached a record level in 2012. Yellowfin tuna was the second largest component of the tuna landings and also reached a record amount. Skipjack tuna landings decreased over time and were at its lowest levels in 2010. Albacore landings rose from a low of 670,000 pounds in 2009 to a record 2 million pounds in 2012.

Source and Calculations: Tuna landing statistics were derived from NOAA Fisheries longline logbook, HDAR Commercial Fish Catch, and Marine Dealer data and was calculated for each gear type. Landings by the longline were derived from the logbook and HDAR Dealer data while the MHI troll, MHI handline, offshore handline, aku boat fisheries and other gear originate from the HDAR Commercial Fish Catch and Dealer data sets. Tuna landings were composed of albacore, bigeye tuna, bluefin tuna, skipjack tuna, yellowfin tuna and other tunas.

	Hawaii tuna landings (1000 pounds)

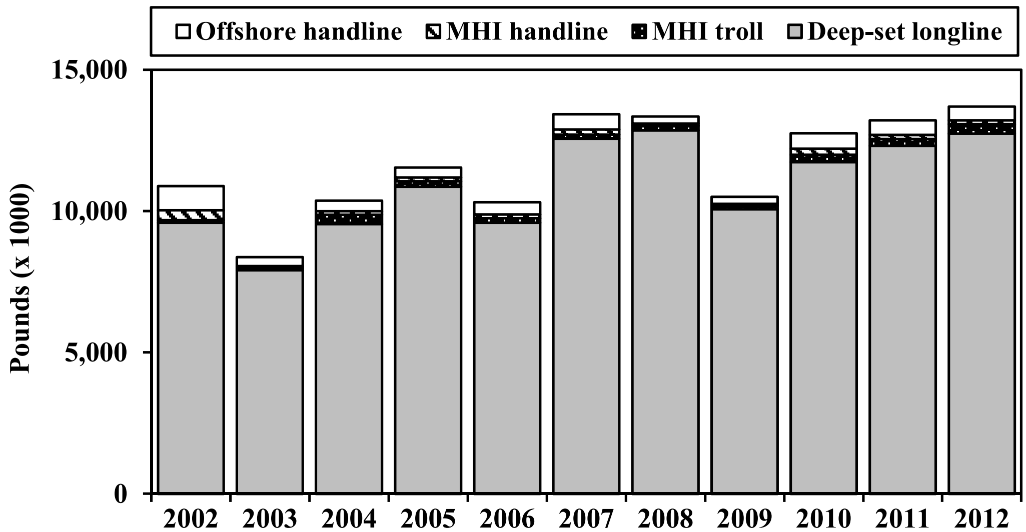
Figure 86. Hawaii bigeye tuna landings by gear type, 2002-2012



Interpretation: Annual bigeye tuna landings increased gradually reaching a record of 14 million pounds in 2012. The deep-set longline fishery is the dominate gear type for bigeye tuna. It accounted for 91% of the total bigeye tuna landings. Landings by the shallow-set longline, MHI troll, MHI, handline and offshore handline varied considerably over the 11-year period but were far below that of the deep-set longline fishery.

Source and Calculations: Bigeye tuna landings statistics were derived from NOAA Fisheries longline logbook, HDAR Commercial Fish Catch, and Marine Dealer data. The gear types summarized for landings of bigeye tuna included the longline, MHI troll, MHI handline, and offshore handline fisheries and the other gear category.

	Hawaii bigeye tuna landings (1000 pounds)						
Year	Deep-set longline	Shallow-set longline	MHI troll	MHI handline	Offshore handline	Other gear	Total

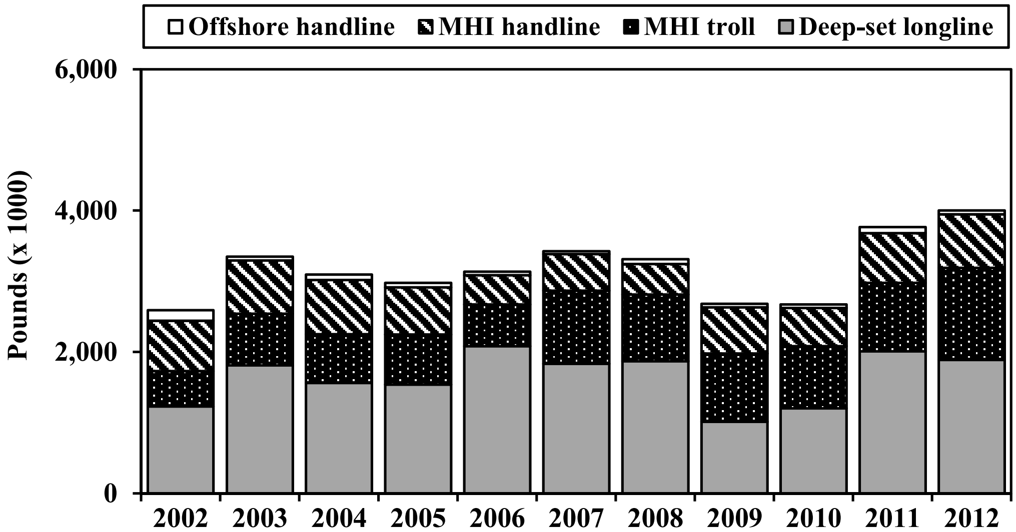
Figure 87. Hawaii yellowfin tuna landings by gear type, 2002-2012



Interpretation: Yellowfin tuna landings rose gradually peaking at 4.1 million pounds in 2012. There were three gear types that contributed to majority of the yellowfin tuna landings. The deep-set longline fishery was the largest fishery landing yellowfin tuna and accounted for 50% of the total landings. The MHI troll and MHI handline fisheries represented 26% and 19% of the yellowfin tuna landings, respectively. The MHI troll fishery was on an increasing trend while there was no pattern for the deep-set longline and MHI handline fisheries.

Source and calculations: Yellowfin tuna landing statistics were derived from NOAA Fisheries longline logbook, HDAR Commercial Fish Catch, and Marine Dealer data. The gear types summarized for landings of yellowfin tuna included the longline, MHI troll, MHI handline, offshore handline fisheries and other gear that included landings from the aku boat fishery.

	Hawaii yellowfin tuna landings (1000 pounds)						
Year	Deep-set longline	Shallow-set longline	MHI troll	MHI handline	Offshore handline	Other gear	Total
2002	1,231	0	500	711	151	68	2,661

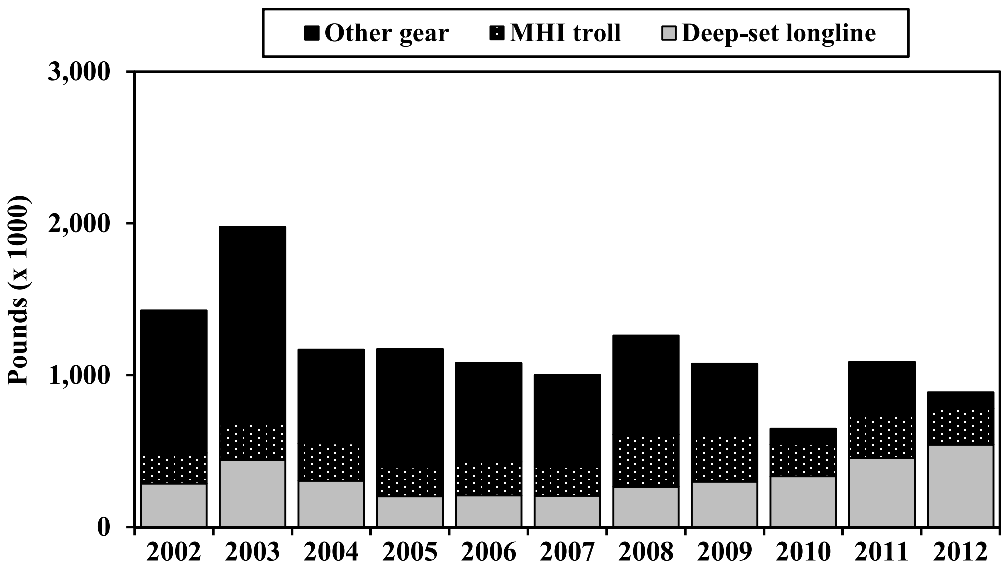
Figure 88. Hawaii skipjack tuna landings by gear type, 2002-2012



Interpretation: Skipjack tuna landings peaked at almost 2 million pounds in 2003 and declined slowly thereafter with a low of 662,000 pounds in 2010. The decline of skipjack tuna landings is a result of the attrition in the aku boat fishery, which was combined with other gear to satisfy confidentiality standards. This decline in skipjack tuna landings was not apparent or as apparent in other fisheries. Increasing skipjack tuna landings by the deep-set longline fishery has made this the largest fishery for this species from 2010. Landings by the MHI troll fishery were stable during the 11-year period.

Source and calculations: Skipjack tuna landing statistics were derived from NOAA Fisheries longline logbook, HDAR Commercial Fish Catch, and Marine Dealer data. The gear types summarized for landings of skipjack tuna included the deep-set longline, shallow-set longline, MHI troll, MHI handline fisheries, and other gear types that contributed a small amount of skipjack tuna and included landings by the aku boat fishery.

	Hawaii skipjack tuna landings (1000 pounds)

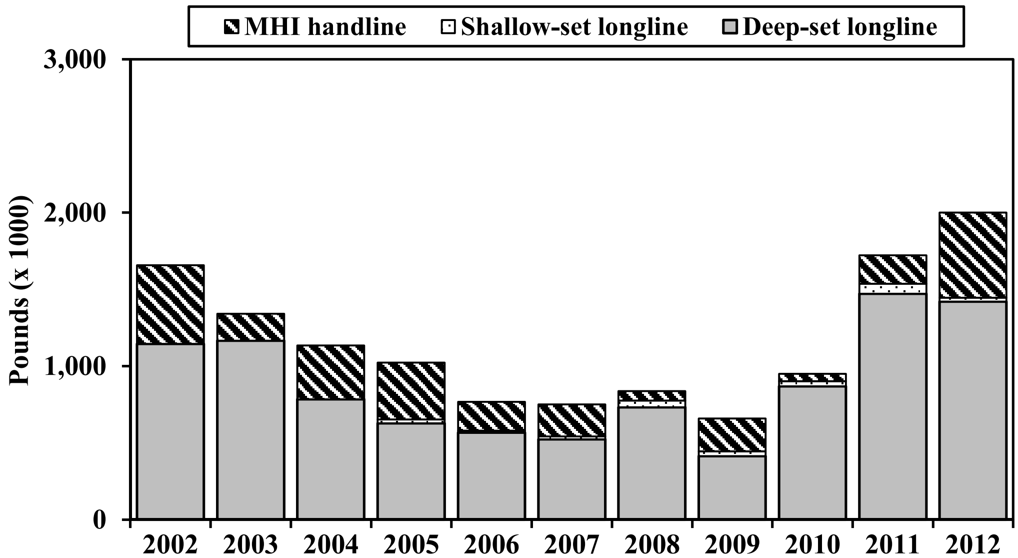
Figure 89. Hawaii albacore landings by gear type, 2002-2012



Interpretation: Albacore landings decreased slowly from 1.6 million pounds in 2002 to 667,000 pounds in 2009, then rose by more than 3-fold to 2 million pounds in 2012. The deep-set longline fishery accounted for 75% of the albacore landings. The MHI handline fishery was the second largest fishery for albacore and represented 22% of the total. Albacore landings by this fishery varied considerably ranging from 48,000 pounds in 2010 to a record 554,000 pounds in 2012. Albacore landings by the shallow-set longline and MHI troll fisheries were small. On rare occasions, the MHI troll fishery has encountered short "runs" of albacore but those landings were negligible in comparison to the deep-set longline and MHI handline fisheries.

Source and calculations: Albacore landing statistics were derived from NOAA Fisheries longline logbook, HDAR Commercial Fish Catch, and Marine Dealer Data. The gear types summarized for landings of albacore included the deep-set longline, shallow-set longline, MHI troll, and MHI handline fisheries.

	Hawaii albacore landings (1000 pounds)

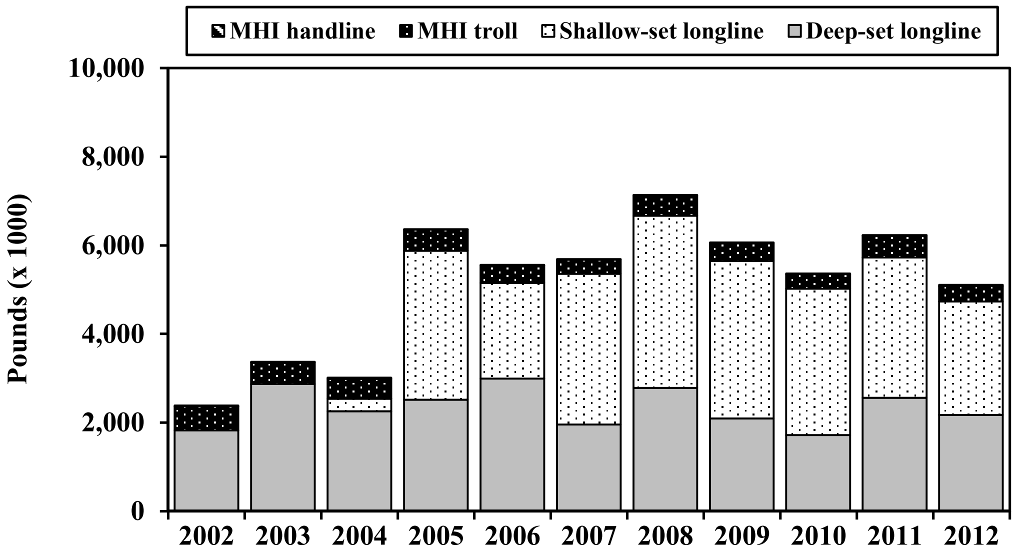
Figure 90. Hawaii commercial billfish landings by gear type, 2002-2012



Interpretation: The largest fisheries for billfish were the deep-set and shallow-set longline fisheries. The most significant event that led to a large increase in billfish landings was the reopening of the shallow-set longline fishery in 2004. Billfish landings, composed predominantly of swordfish, by the shallow-set longline fishery increased dramatically the following year. Billfish landings by the deep-set longline fishery were mostly marlins. The MHI troll fishery landed a much lower volume of billfish that was composed primarily of blue marlin.

Source and calculations: Billfish landing statistics were derived from NOAA Fisheries longline logbook, HDAR Commercial Fish Catch, and Marine Dealer data and was calculated for each gear type. Landings by the longline were derived from the logbook and HDAR Dealer data while the MHI troll, MHI handline, offshore handline, aku boat fisheries and other gear originate from the HDAR Fish Catch and Dealer data sets. The billfish group was composed of swordfish, blue marlin, striped marlin, spearfish, sailfish, black marlin, and other marlins.

	Hawaii billfish landings (1000 lbs)						
Year	Deep-set longline	Shallow-set longline	MHI troll	MHI handline	Offshore handline	Other gear	Total

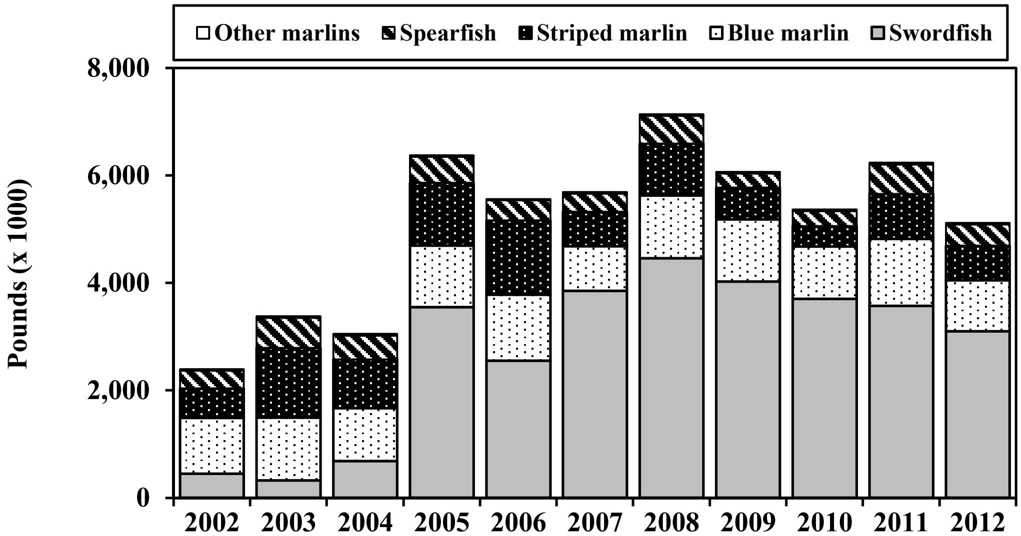
Figure 91. Species composition of the billfish landings, 2002-2012



Interpretation: The billfish landings consisted mostly of swordfish, blue marlin, and striped marlin with smaller catches of spearfish and other marlins. Swordfish landings dominated billfish landings from 2005 with the reopening of the shallow-set longline fishery in 2004. Blue marlin and striped marlin were the next two largest components of the billfish landings followed by spearfish. Small catches of other marlins were composed of sailfish and black marlin.

Source and calculations: The billfish landing statistics were derived from NOAA Fisheries longline logbook, HDAR Commercial Fish Catch, and Marine Dealer data and was calculated for each species. The gear types summarized for each species include landings from the longline, MHI troll, MHI handline, offshore handline, aku boat fisheries, and other gear category.

	Hawaii billfish landings (1000 lbs)

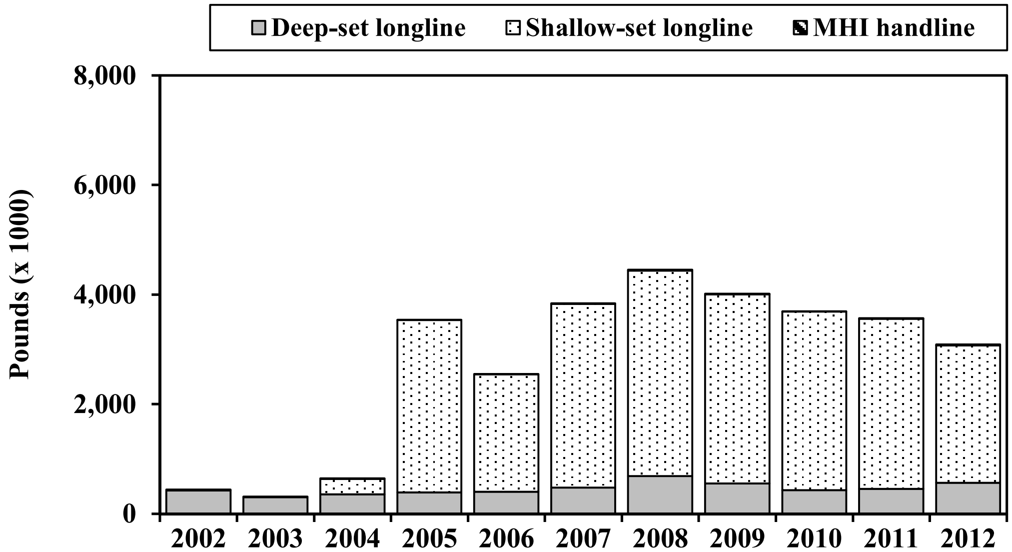
2012	3,094	951	648	386	30	5,109
Average	**2,747.5**	**1,081.3**	**851.5**	**409.7**	**30.4**	**5,120.3**
SD	**1,535.8**	**131.8**	**327.1**	**105.3**	**3.9**	**1,521.1**

Figure 92. Hawaii swordfish landings, 2002-2012



Interpretation: Swordfish landings were low in 2002 and 2003 due to a prohibition on targeting swordfish by the longline fishery from high sea turtle interaction rates with shallow-set longline gear. Swordfish landings increased marginally in 2004 with the shallow-set longline fishery reopening under several new regulations intended to reduce sea turtle interactions. Swordfish landings then rose rapidly, peaking at 4.5 million pounds in 2008 then declined gradually to 3.1 million pounds in 2012. The shallow-set longline fishery accounted for 83% of the total swordfish landings. Although deep-set longline landings of swordfish were higher in recent years, it only represented 17% of the landings. Swordfish landings by the MHI handline fishery were negligible.

Source and calculations: Swordfish landing statistics were derived from NOAA Fisheries longline logbook, HDAR Commercial Fish Catch, and Marine Dealer data. The gear types summarized for landings of swordfish included the deep-set longline, shallow-set longline, and MHI troll fisheries and other gear.

	Swordfish landings (1000 lbs)

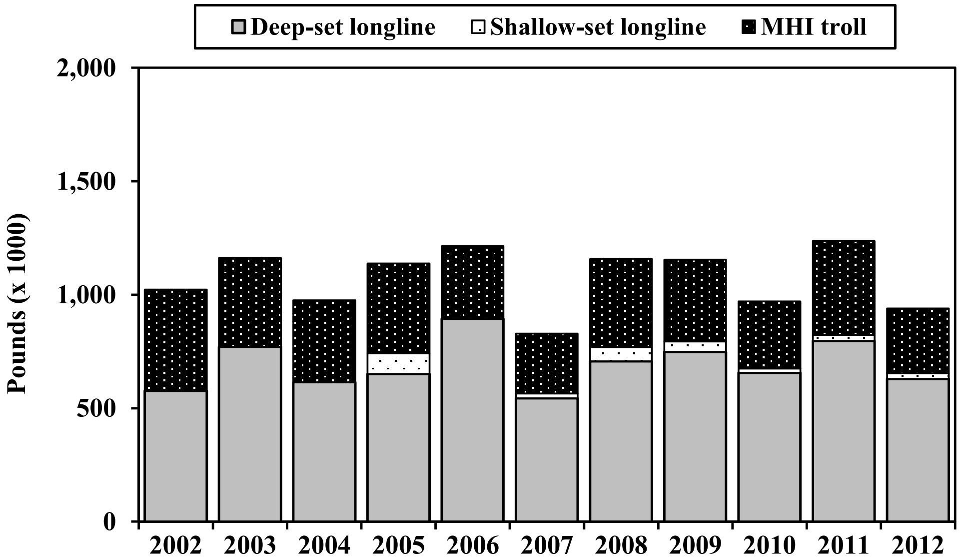
Figure 93. Hawaii blue marlin landings by gear type, 2002-2012



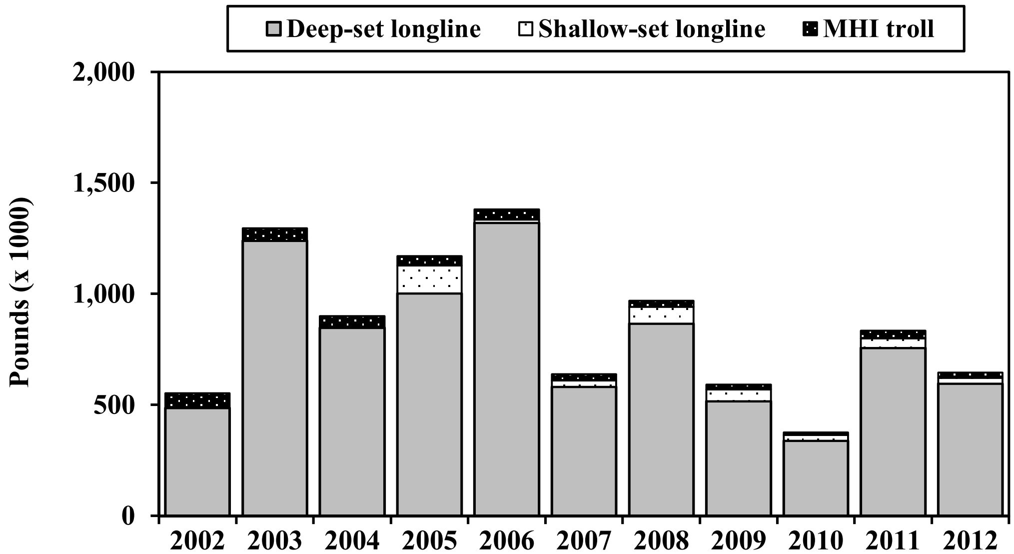
Interpretation: Blue marlin landings were relatively stable during 2002-2012, ranging from 834,000 pounds in 2007 to 1.2 million pounds in 2006 and 2011. The two fisheries that accounted for majority of blue marlin landings were the deep-set longline and MHI troll fisheries which represented 64% and 33% of the marlin landings, respectively. Blue marlin landings by the shallow-set longline and handline fisheries were relatively small in comparison.

Source and calculations: Blue marlin landing statistics were derived from NOAA Fisheries longline logbook, HDAR Commercial Fish Catch, and Marine Dealer data. The gear types summarized for landings of blue marlin included the deep-set longline, shallow-set longline, MHI troll, MHI handline, offshore handline fisheries and other gear category.

	Blue marlin landings (1000 lbs)						
Year	Deep-set longline	Shallow-set longline	MHI troll	MHI handline	Offshore handline	Other gear	Total
2002	578	0	446	6	3	2	1,035
2003	772	0	390	5	1	4	1,172
2004	616	0	360	5	0	5	986
2005	652	90	396	6	1	2	1,147
2006	895	0	320	4	3	1	1,223
2007	545	21	263	2	1	2	834
2008	708	62	388	3	0	4	1,165
2009	749	45	362	2	0	1	1,159
2010	657	18	296	2	1	1	975
2011	797	27	414	4	1	4	1,247
2012	630	26	285	4	1	5	951
Average	**690.8**	**26.3**	**356.4**	**3.9**	**1.1**	**2.8**	**1,081.3**
SD	**104.5**	**29.2**	**58.2**	**1.5**	**1.0**	**1.6**	**131.8**

Blue marlin landings by the longline fishery are nominal estimates that do not account for misidentification problems. The results of the marlin misidentification problem showed that striped marlin in longline logbooks were misidentified as blue marlin in a Pelagic Fisheries Research Program (PFRP) project. Thus, the general pattern was blue marlin were overreported in logbooks. Therefore, nominal blue marlin landing estimates for the longline fishery are probably inflated.

Figure 94. Hawaii striped marlin landings by gear type, 2002-2012



Interpretation: Striped marlin landings varied over the 11-year period, ranging from a peak of 1.4 million pounds in 2006 to a low of 376,000 pounds in 2010. Striped marlin was landed primarily by the deep-set longline fishery. This fishery was responsible for over 90% of the striped marlin landings. The shallow-set longline fishery was the second largest producer of striped marlin followed by the MHI troll fishery. Most of the fisheries landing striped marlin appeared to be on a downward trend.

Source and Calculations: Striped marlin landing statistics were derived from NOAA Fisheries longline logbook, HDAR Commercial Fish Catch, and Marine Dealer data. The gear types summarized for catches of striped marlin included the deep-set longline, shallow-set longline, MHI troll, MHI handline, offshore handline fisheries and other gear category.

Striped marlin landings by the longline fishery are nominal estimates which do not account for misidentification problems. The results of the marlin misidentification problem showed that striped marlin in longline logbooks were misidentified as blue marlin in a Pelagic Fisheries Research Program (PFRP) project. Thus, the nominal striped marlin landing estimates for the longline fishery are negatively biased. Thus, the longline landings presented in this report are a conservative estimate.

	Striped marlin landings (1000 lbs)

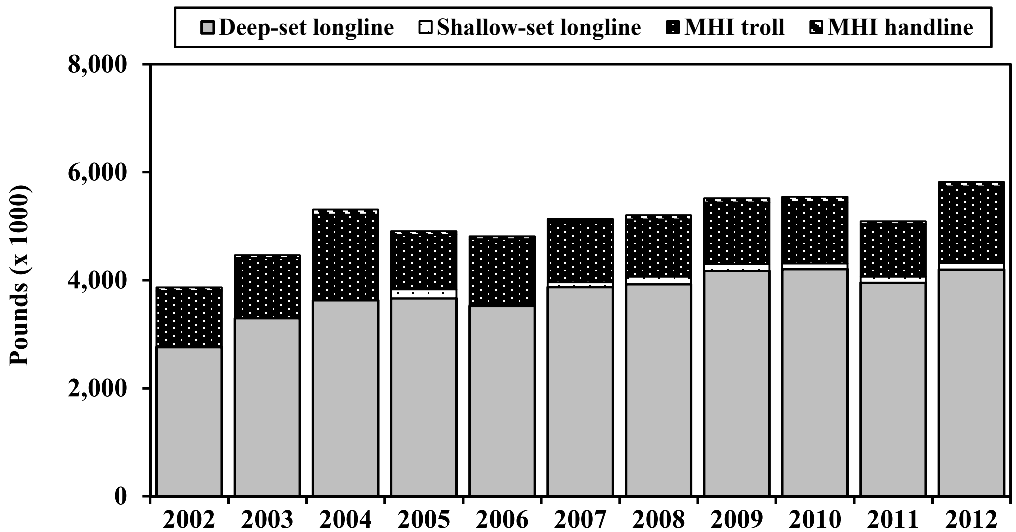
Figure 95. Hawaii commercial landings of other PMUS by gear type, 2002-2012



Interpretation: The landings of other PMUS increased gradually from 4 million pounds in to 5.9 million pounds in 2012. Most of the growth was attributed primarily to increased landings by the deep-set longline fishery. The MHI troll fishery was second highest contributor to other PMUS landings and was reasonably stable. Other PMUS landings by the MHI handline and offshore handline fisheries were much lower than the longline and MHI troll fisheries.

Source and calculations: Other pelagic PMUS landing statistics were derived from NOAA Fisheries longline logbook, HDAR Commercial Fish Catch, and Marine Dealer data and was calculated for each gear type. Landings by the longline fishery were derived from the logbook and HDAR Dealer data while the MHI troll, MHI handline, offshore handline, and other gear originate from the HDAR Fish Catch and Dealer data sets. The other PMUS category includes mahimahi, moonfish, oilfish, ono, pomfret, and PMUS sharks.

	Landings of other PMUS by gear type (1000 lbs)						
Year	Deep-set longline	Shallow-set longline	MHI troll	MHI handline	Offshore handline	Other gear	Total

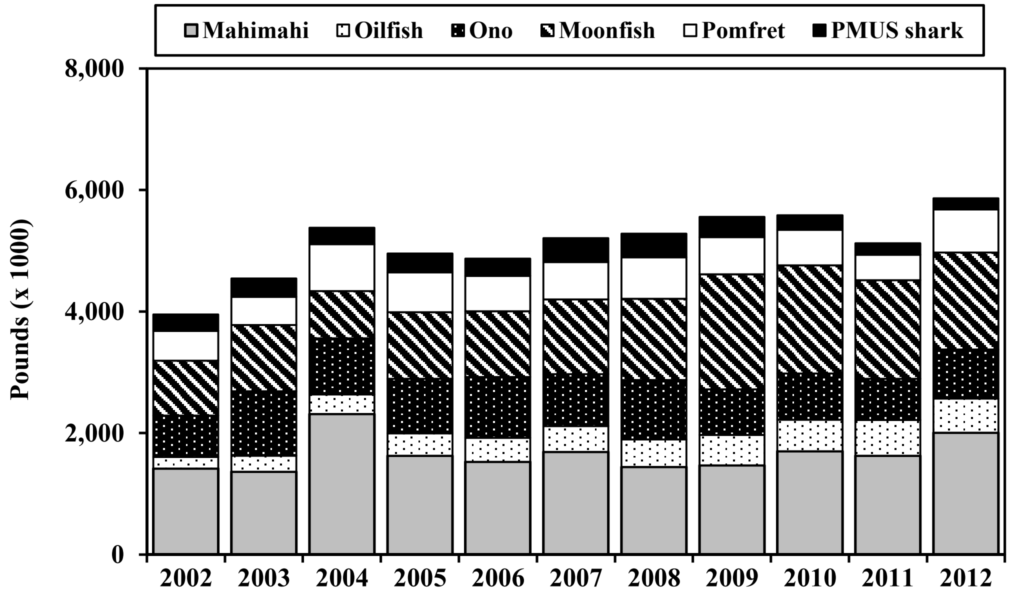
Figure 96. Species composition of other PMUS landings, 2002-2012



Interpretation: Mahimahi, ono, and moonfish were the three largest components of other PMUS landings. Landings of mahimahi and moonfish were above their respective long-term averages in 2012. Ono landings fluctuated over the past 11 years and were below its long-term average from 2008. Though pomfret and oilfish landings were lower than those species mentioned above, the landings of these two species have experienced notable rates in increase from 2002 through 2012. Shark landings gradually decreased after its peak in 2007.

Source and calculations: The other pelagic PMUS landing statistics were derived from NOAA Fisheries longline logbook, HDAR Commercial Fish Catch, and Marine Dealer data and was calculated for each species. The gear types summarized for each species include landings from the longline, MHI troll, MHI handline, offshore handline, and other gear category.

	Landings of other PMUS by species (1000 lbs)

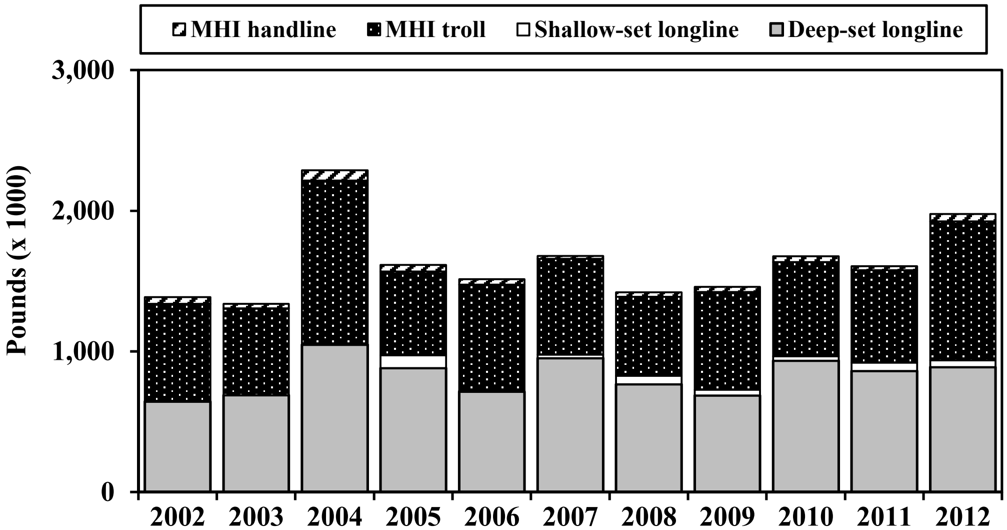
Figure 97. Hawaii mahimahi landings by gear type, 2002-2012



Interpretation: Mahimahi landings peaked at 2.3 million pounds in 2004. Landings were relatively stable through 2001 and rose to 2 million pounds in 2012. The deep-set longline and MHI troll fisheries accounted for 94% of mahimahi landings. The shallow-set longline, MHI handline, offshore handline, and other gear type landings of mahimahi were very low.

Source and calculations: Mahimahi landing statistics were derived from NOAA Fisheries longline logbook, HDAR Commercial Fish Report and Marine Dealer data. The gear types summarized for mahimahi landings included the deep-set and shallow-set longline, MHI troll, MHI handline, offshore handline fisheries and the other gear category.

	Mahimahi landings (1000 lbs)

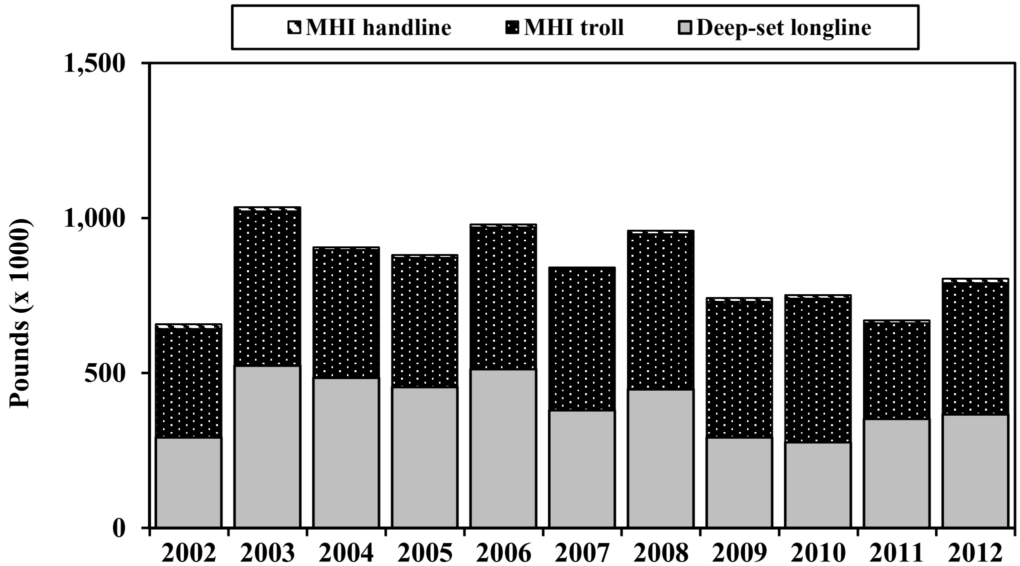
Figure 98. Hawaii wahoo (ono) landings by gear type, 2002-2012



<u>Interpretation:</u> Ono landings peaked above 1 million pounds in 2003 and 2006. Ono landings were below their long-term average, but stable from 2009 through 2012. The deep-set longline and troll fisheries were the main contributors to ono landings. The deep-set longline fishery had higher landings in the early part of the time series and was replaced by the MHI troll fishery in the recent years.

<u>Source and calculations:</u> Ono landing statistics were derived from NOAA Fisheries longline logbook, HDAR Commercial Fish Report and Marine Dealer data. The gear types summarized for landings of ono included the deep-set and shallow-set longline, MHI troll, and MHI handline fisheries. The total column also contains small ono landings by the offshore handline fishery and other gear category.

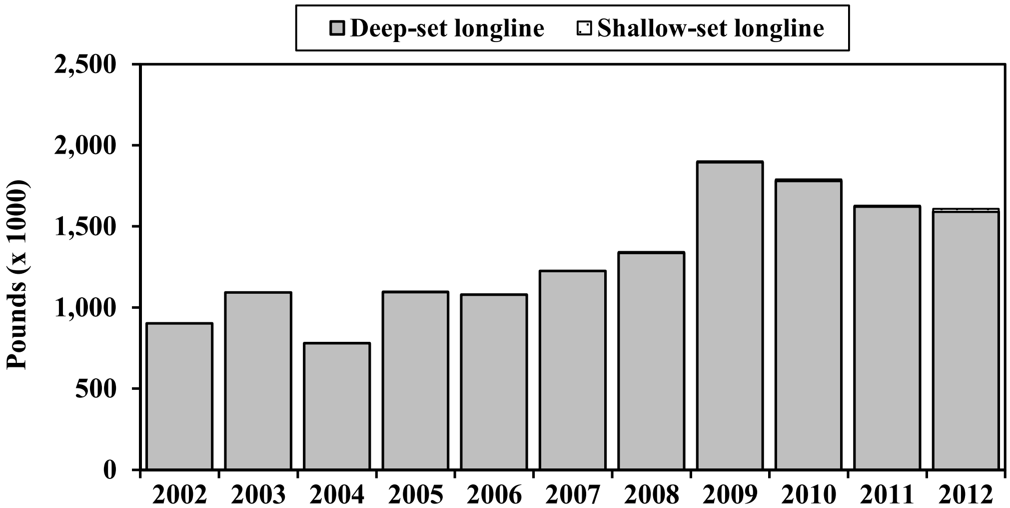
Figure 99. Hawaii moonfish landings, 2002-2012



Interpretation: Moonfish are unique among the PMUS because they are caught exclusively by the longline fishery with the deep-set sector accounting for almost all of landings. Although moonfish landings by the shallow-set longline fishery were increasing, they were still well below the level landed by the deep-set sector. Landings rose from 780,000 pounds in 2004, peaked at 1.9 million pounds in 2009 then declined to 1.6 million pounds in 2011 and 2012.

Source and calculations: Moonfish landing statistics were derived from NOAA Fisheries longline logbook and HDAR Commercial Marine Dealer data. There were no landings of moonfish in the HDAR Commercial Fish Report data by the MHI troll, MHI handline, and offshore handline fisheries.

	Moonfish landings (1000 lbs)

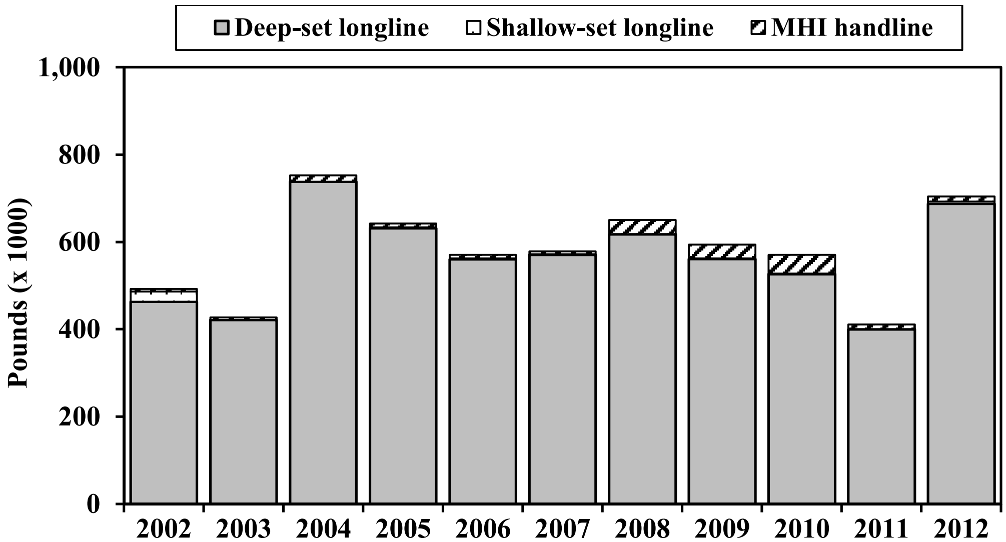
Figure 100. Hawaii pomfret landings, 2002-2012



Interpretation: Pomfret landings ranged from 422,000 pounds in 2011 to 771 pounds in 2004. Pomfret landings rose in 2012 by 68% from 2011; the longline fishery was responsible for 93% of the total pomfret landings. The MHI handline, offshore handline, shallow-set longline fisheries and other gear types contributed to the rest of the pomfret landings. There was no trend with respect to total pomfret landings from 2002-2012.

Source and calculations: Pomfret landing statistics were derived from NOAA Fisheries longline logbook and HDAR Commercial Fish Catch, and Marine Dealer data. The gear types summarized for landings of pomfrets included the longline, MHI troll, MHI handline fisheries, and other gear category.

	Pomfret landings (1000 lbs)

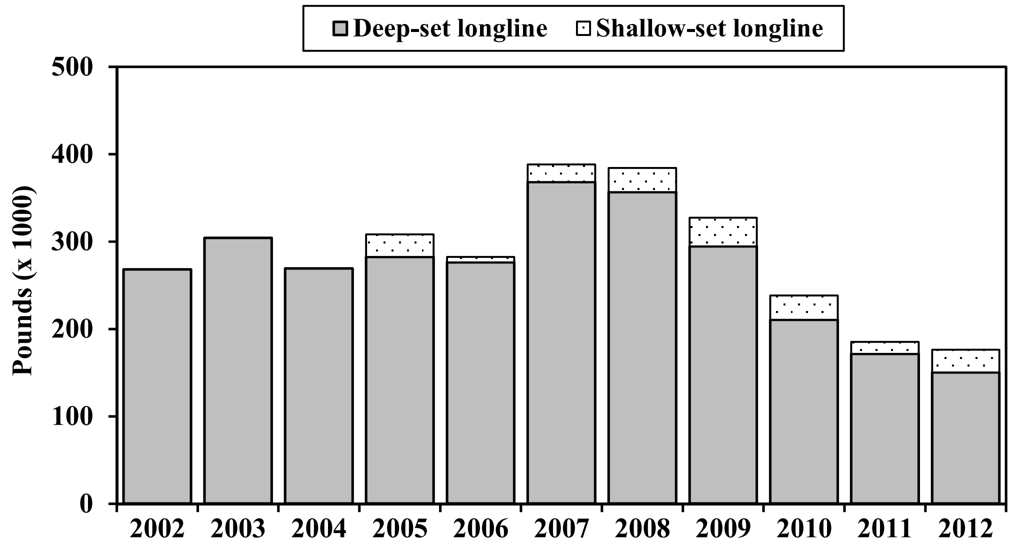
Figure 101. Hawaii PMUS shark landings, 2002-2012



Interpretation: Sharks were landed almost exclusively by the deep-set longline fishery. Shark landings were relatively stable from 2002 through 2006, then peaked in 2007, and decreased to a low in 2012. The deep-set longline fishery accounted for 94% of the shark landings. Since mako and thresher sharks had markets for fillets and fish steaks, they were the species typically landed by the longline fishery. Most of the other shark species were released.

Source and calculations: Shark catch (in number of fish kept) were derived from NOAA Fisheries longline logbook. The HDAR Dealer data included sharks which were typically landed headed and gutted and were raised to an estimated whole weight. The number of sharks was multiplied by the mean whole weight to yield shark landings. For shark species with no the weight data from HDAR Dealer data, landings were extrapolated by using an average length calculated from the observer data that was converted to weight which was then used to multiply number of fish as a crude method to estimate shark biomass.

	PMUS shark landings (1000 lbs)			
Year	Deep-set longline	Shallow-set longline	Non-Longline	Total

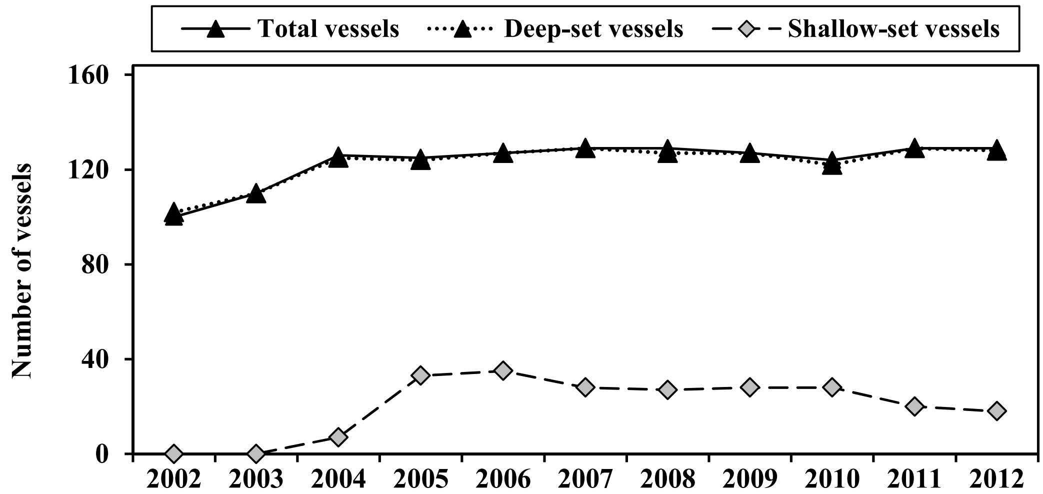
Figure 102. Number of Hawaii-based longline vessels, 2002-2012



Interpretation: There were 129 active Hawaii-based longline vessels in 2012, the same number of vessels as in the previous year. Vessel activity was lowest in 2002 and 2003 when shallow-set longline fishing was prohibited. The increase in vessel activity in 2003 and 2004 is from California-based vessels migrating back to Hawaii due to the reopening of the shallow-set longline fishery in April 2004 under a new set of regulations intended to reduce the number of sea turtle interactions. The total number and number of deep-set vessels varied little from 2004 through 2012, but the pattern for shallow-set vessel activity was quite different. Only 7 vessels chose to embark on shallow-set trips in 2004, but this number rose dramatically in the following year peaking at 35 vessels in 2006. The number of shallow-set vessels declined slowly to 18 vessels in 2012. Almost all shallow-set longline vessels switch to deep-set longline fishing after the swordfish season.

Source and calculations: The number of vessels was compiled from NMFS federal longline logbook data. The vessel summary was based on haul date. The vessel counts were based on whether they went deep-set or shallow-set longline fishing. A deep-set trip was defined as one which fishing operations set 15 or more hooks between floats while a shallow-set trip was characterized by sets with less than 15 hooks between floats. Shallow-set effort was prohibited in 2002 and 2003. Almost all vessels that went shallow-set longline fishing switched to deep-set longline fishing at some time of the year.

Year	Deep-set	Shallow-set	Total vessels
2002	102	0	100
2003	110	0	110
2004	125	7	126

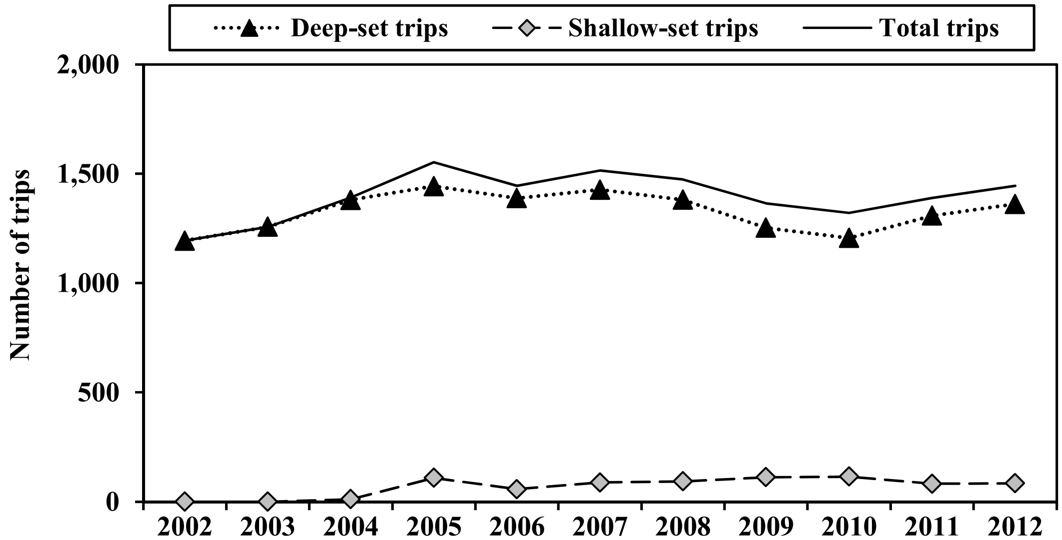
SD	**8.7**	**12.7**	**9.4**

Figure 103. Number of trips by the Hawaii-based longline fishery, 2002-2012



Interpretation: The Hawaii-based longline fleet made 1,361 trips in 2012. The total number of trips was lowest in 2002 and 2003 during which time only deep-set longline fishing was allowed. Trips increased in 2004 with the return of longline vessels that were in California and peaked in 2005 as shallow-set longline fishing picked up. The number of trips remained about the same thereafter. Deep-set trips made up 95% of the total number of trips during 2002-2012. Shallow-set trips are highest in the early part of each year when swordfish season is at its peak.

Source and calculations: The number of trips was compiled from NMFS federal longline logbook data. The trip summary was based on haul date. The trip type was separated into deep-set or shallow-set. A deep-set trip was defined as one in which fishing operations set 15 or more hooks between floats while a shallow-set trip was characterized by sets with less than 15 hooks between floats. Shallow-set effort was prohibited in 2002 and 2003.

	Hawaii longline trip activity		
Year	Total trips	Deep-set trips	Shallow-set trips
2002	1,194	1,194	0
2003	1,257	1,257	0
2004	1,391	1,380	11

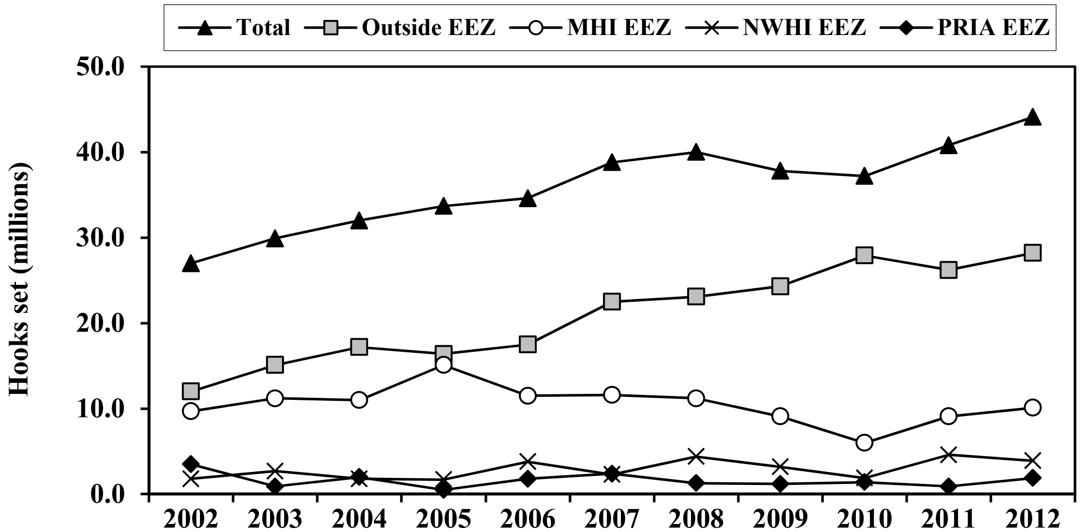
SD	**107.8**	**87.8**	**44.6**

Figure 104. Number of hooks set by the Hawaii-based deep-set longline fishery, 2002-2012



Interpretation: The total number of hooks set by the Hawaii-based deep-set longline fishery increased steadily from 27 million hooks in 2002 to a record 44.1 million hooks in 2012. Much of the increase in effort is due to higher effort outside the EEZ. Hooks set outside the EEZ represented 64% of the total effort in 2012. Hooks set in the MHI EEZ was relatively stable and was close to its long-term average in 2012. Hooks set in the NWHI EEZ and PRIA EEZ was relatively low compared to effort outside the EEZ and MHI EEZ.

Source and calculations: Number of hooks set was compiled from NMFS federal longline logbook data collected from 2004 to 2012. The Hawaii-based longline fishery was separated into deep-set or shallow-set sectors. The set type was based the number of hooks between floats with a deep-set defined as a fishing operation with 15 or more hooks between floats and a shallow-set characterized by having less than 15 hooks between floats. The time series for the shallow-set sector was truncated since this type of longline fishing was prohibited in 2002 and 2003. The summary of hooks set was based on date of haul and grouped into general areas of operation, i.e., Main Hawaiian Islands EEZ, Northwestern Hawaiian Islands EEZ, Pacific Remote Island Area EEZ, and the Outside of the U.S. EEZs.

	Number of hooks set by area (milions)

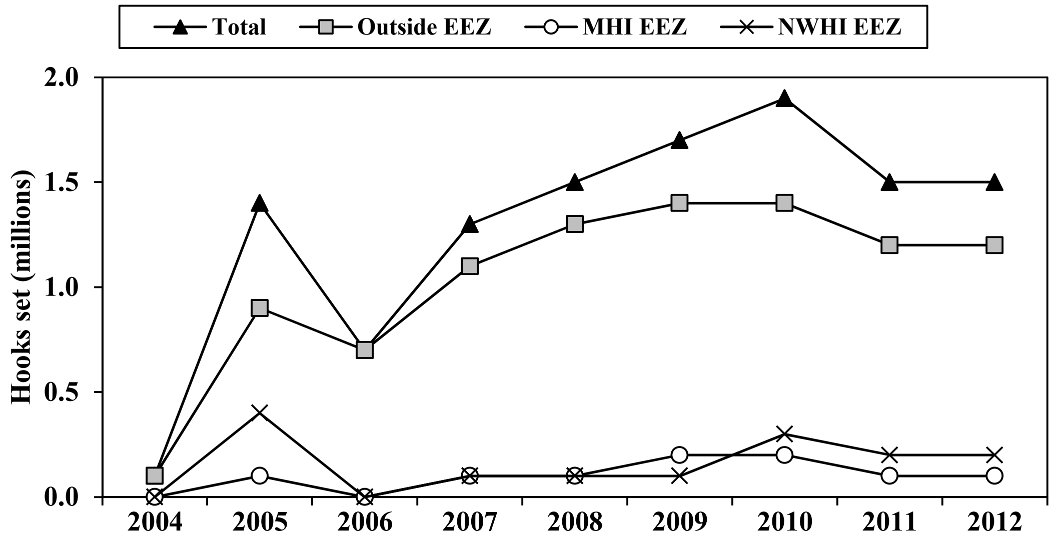
Figure 105. Number of hooks set by the Hawaii-based shallow-set longline fishery, 2004-2012



<u>Interpretation:</u> The total number of hooks set by the Hawaii-based shallow-set longline fishery was low when it was first reopened in 2004 since fishermen were uncertain how successful their operations would be under the new set of regulations and the timing of the reopening occurring near or just past the peak of a typical swordfish season. Effort increased in 2005 as fishermen adapted to the change in regulations. However, the shallow-set sector effort was curtailed when it reached the loggerhead sea turtle limit in March 2006. The shallow-set fishery was then closed for the rest of the year. The number of hooks set peaked at 1.9 million hooks in 2010, decreased the flowing year, and remained the same in 2012.

Most of the hooks set by the shallow-set longline fishery were outside the EEZ (80%). Much less effort was observed in the NWHI EEZ (12%) and the MHI EEZ (8%). The shallow-set effort in the NWHI EEZ and MHI EEZ usually occur later in the swordfish season when fish migrate closer the Hawaiian Islands.

<u>Source and calculations:</u> Number of hooks set was compiled from NMFS federal longline logbook data collected from 2004 to 2012. The Hawaii-based longline fishery was separated into deep-set or shallow-set sectors. The set type was based the number of hooks between floats with a deep-set defined as a fishing operation with 15 or more hooks between floats and a shallow-set characterized by having less than 15 hooks between floats. The time

Interpretation: With the exception of swordfish, the largest catches were made by deep-set sector of the longline fishery. Catches for most species were usually highest outside the U.S. EEZ for both sectors. Bigeye tuna catches by the deep-set sector were higher in the latter part of the time series, while swordfish catches by the shallow-set sectors were trending down after its peak in 2005.

Source and calculations: Catches (number of fish) by area were compiled from NMFS federal longline logbook data. The catch tables are based on date of haul and include fish that were kept and released. The shallow-set sector of the Hawaii-based longline fishery was reopened in March 2004. The set type was based the number of hooks between floats with a deep-set defined as a fishing operation with 15 or more hooks between floats and a shallow-set characterized by having less than 15 hooks between floats. Longline vessel operators are required to declare what set type they plan to make prior to leaving on a trip. The bolded numbers in the above tables show the area with the highest catch for a particular species in each area. The bolded numbers in the total catch table is the year which the record high catch was made for each species of fish.

Interpretation: The deep-set sector targets bigeye tuna, while the shallow-set sector fishes for swordfish although both sectors catch and land a variety of pelagic species. The mean weight of fish landed by the shallow-set sector was larger for most of the major species. Bigeye tuna from the deep-set sector was at its long-term mean weight in 2011 and 2012 and has been greater than 80 lbs from 2004. Mean weight of swordfish by the shallow-set sector varied from 2004 with the average weight at its long-term value in 2012.

Source and calculations: Average weight of the longline landings was summarized from the HDAR, State Commercial Marine Dealer data identified as landed by longline fishing during 2002 to 2012. Swordfish and sharks were landed headed and gutted. In December 2004, the Honolulu Auction required fishers to gill and gut tunas and mahimahi that weighed more than 20 pounds and marlins greater than 40 pounds. When fish were processed prior to sale, e.g., headed and gutted, gilled and gutted, a conversion factor was applied to convert it to an estimated whole weight. Discarded fish were not represented in the size summaries. Average weight statistics were also calculated for deep-set and shallow-set longline sectors. The set type was based the number of hooks between floats with a deep-set defined as a fishing operation with 15 or more hooks between floats and a shallow-set characterized by having less than 15 hooks between floats. Longline vessel operators are required to declare what set type they plan to make prior to leaving on a trip. Each species needed a minimum of 20 samples within a month of each RFMO area, i.e., WCPO or EPO, in order to calculate a mean weight. If this criteria was not met, the time strata was increased to a quarter, year or multi-year period until there were enough samples to calculate a mean weight. Some species which were landed in low numbers needed to be aggregated to a multi-year period. Consequently, their respective annual mean weights are the same from year to year or repeat over time.

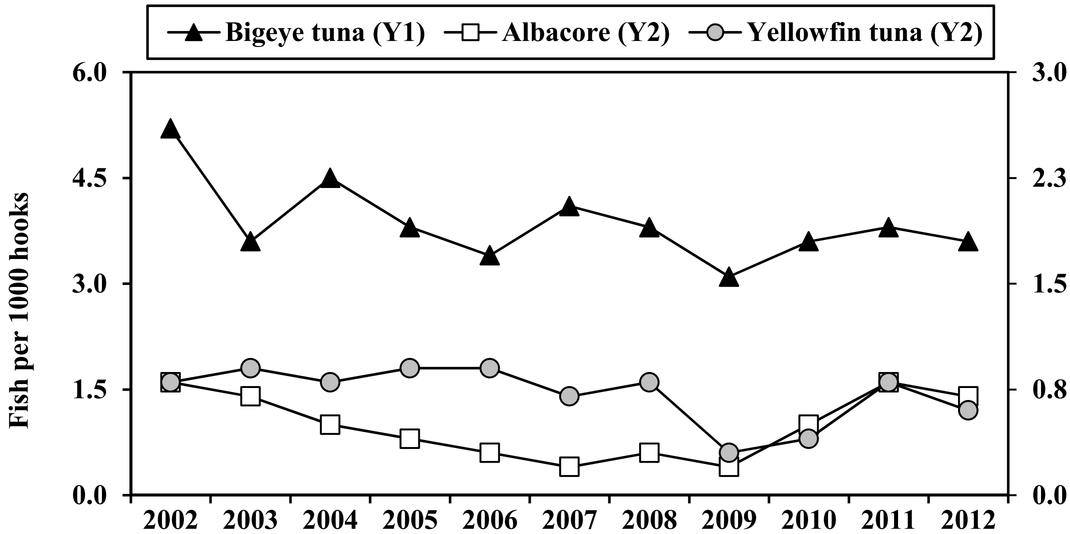
Interpretation: Released, retained and total catch by the Hawaii-based longline fishery was measured in number of fish. Since fishing techniques and target species were different between the deep-set and shallow-set sectors of the longline fishery, the catch table was split into their respective sectors. The disposition of sharks was significantly different from tunas, billfish, and other PMUS. Therefore, sharks were separated into a group of its own.

The number and percentage of fish released by the deep-set sector of the longline fishery in 2012 was 65,271 fish and 12%, respectively. The percentage of tuna, billfish and other PMUS released by the deep-set sector of the longline fishery was only 2%. Bigeye tuna, the target species of the deep-set sector, had the highest number of fish released although the rate of fish released was only 1.4%. Although billfish and other PMUS are not targeted, these species are highly marketable and also have low rates of release (1.4% and 0.7%, respectively). In contrast to tunas, billfish and other PMUS, sharks had the highest number and percentage of fish released. There were 56,456 sharks released, which represented 97.9% of the total sharks caught by the deep-set sector.

The number of fish released by the shallow-set sector of the longline fishery was lower compared to the deep-set sector, but the rate of fish released was higher; 8,942 fish and 28%, respectively. The higher release rate by the shallow-set sector may be related conserving space for swordfish and the limited shelf life of incidental catch of other marketable species of fish. The percentage of tuna, billfish and other PMUS released by the shallow-set sector of the longline fishery was 8.6% in 2012. Swordfish, the target species of the shallow-set sector, had the highest number of non-shark catch released. However, the percentage of swordfish released (8.8%) was close to the total non-shark release rate. In contrast to tunas, billfish and other PMUS, sharks had the highest number and percentage of fish released. There were 8,942 sharks released which represented 97.6% of the total sharks caught by the shallow-set sector. With the exception of mako shark, other shark species have no market so they are released.

Source and calculations: Longline released catch, retained catch and total catch along with their respective percentages were compiled from NMFS longline logbook data. Longline catch was summarized on date of haul. The set type was based the number of hooks between floats with a deep-set defined as a fishing operation with 15 or more hooks between floats and a shallow-set characterized by having less than 15 hooks between floats. Longline vessel operators are required to declare what set type they plan to make prior to leaving on a trip.

Figure 106. Hawaii longline CPUE for major tunas on tuna trips, 2002-2012



Interpretation: Bigeye tuna CPUE was consistently higher than those for albacore or yellowfin tuna. Bigeye tuna CPUE was 5.2 in 2002, declined the following year, and remained relatively steady ranging between 3.1 and 4.5 in the following years. Albacore is caught incidentally or seldom targeted, therefore its CPUE is much lower than bigeye tuna. Albacore CPUE declined from 2002 through 2009 and rose back to that level in 2011. CPUE for yellowfin tuna was steady from 2002 through 2008, dropped the following two years and recover in 2011 and 2012.

Source and calculation: Tuna CPUE was compiled from NMFS longline logbook data and summarized on date of haul. CPUE was measured as number of fish caught (kept + released) per 1000 hooks. Set type CPUE summaries were based the number of hooks between floats with a deep-set defined as a set with 15 or more hooks between floats and a shallow-set characterized by having less than 15 hooks between floats. Longline vessel operators are required to declare what set type they plan to make prior to leaving on a trip.

	Deep-set longline CPUE (fish per 1000 hooks)		
Year	Bigeye tuna	Albacore	Yellowfin tuna
2002	5.2	0.8	0.8

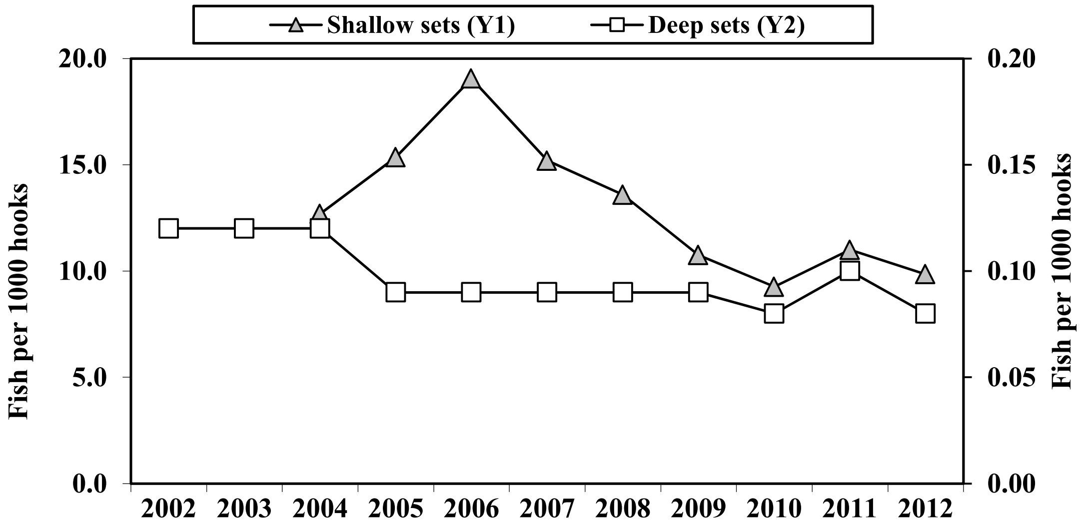
SD	**0.57**	**0.23**	**0.20**

Figure 107. Hawaii longline swordfish CPUE by trip type, 2002-2012



Interpretation: Shallow-set longline fishing was prohibited in 2002 and 2003 due to sea turtle conservation measures then reopened under a new set of regulations with intentions to reduce sea turtle interactions in April 2004. A few shallow-set trips were made before the end of the year and had respectable swordfish CPUEs (Y1 axis) under the new regulations. In 2005, the first complete year since its reopening, the shallow-set sector managed to equal a pre-closure CPUE of 15.3 fish per 1000 hooks attained back in 1991. Although shallow-set CPUE for swordfish was a record 19.0 in 2006, it was only because the shallow-set fishery was closed in March due to reaching the limit of 17 loggerhead turtle interactions. This prohibited this sector from fishing for the remainder of the year when shallow-set CPUE for swordfish is typically lower. Swordfish CPUE for the shallow-set fishery decreased to its lowest level at 9.3 in 2010 and remained low the following two years.

Deep-set longline swordfish CPUEs (Y2 axis) were more than 100 times lower compared to shallow-set longline swordfish CPUEs. Deep-set swordfish CPUE was slightly higher in the earlier period, decreased in 2005 and remained constant thereafter.

Source and calculation: Longline swordfish CPUE was compiled from NMFS longline logbook data and summarized based on date of haul. CPUE was based on number of swordfish caught (kept + released) divided by the number of hooks set. Set type CPUE summaries were based the number of hooks between floats with a deep-set defined as a set with 15 or more hooks between floats and a shallow-set characterized by having less than 15 hooks between floats. Longline vessel operators are required to declare what set type they plan to make prior to leaving on a trip.

	Swordfish CPUE

Figure 108. Longline striped marlin CPUE by trip type, 2002-2012

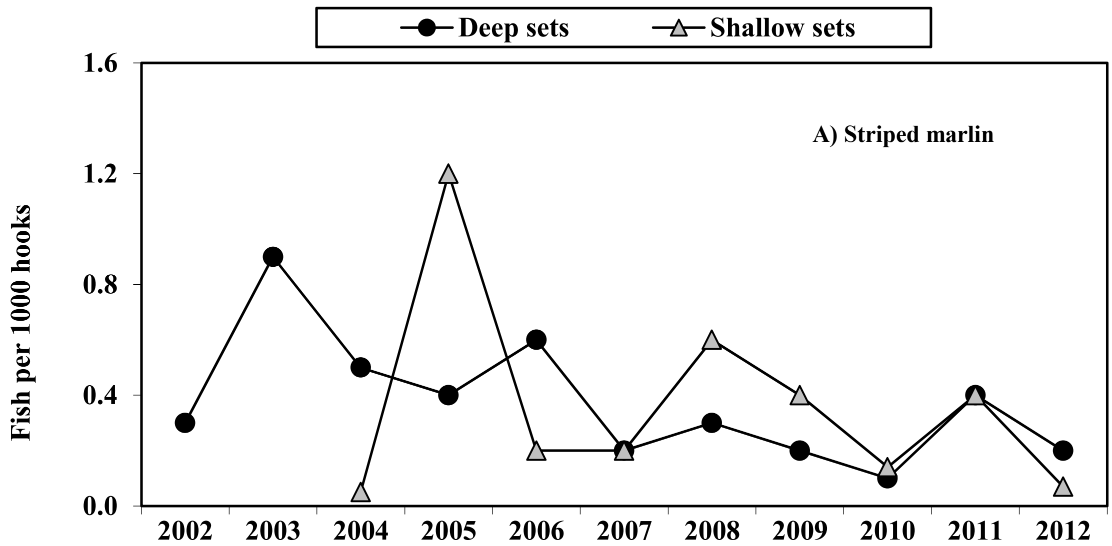

Figure 109. Longline blue marlin CPUE by trip type, 2002-2012

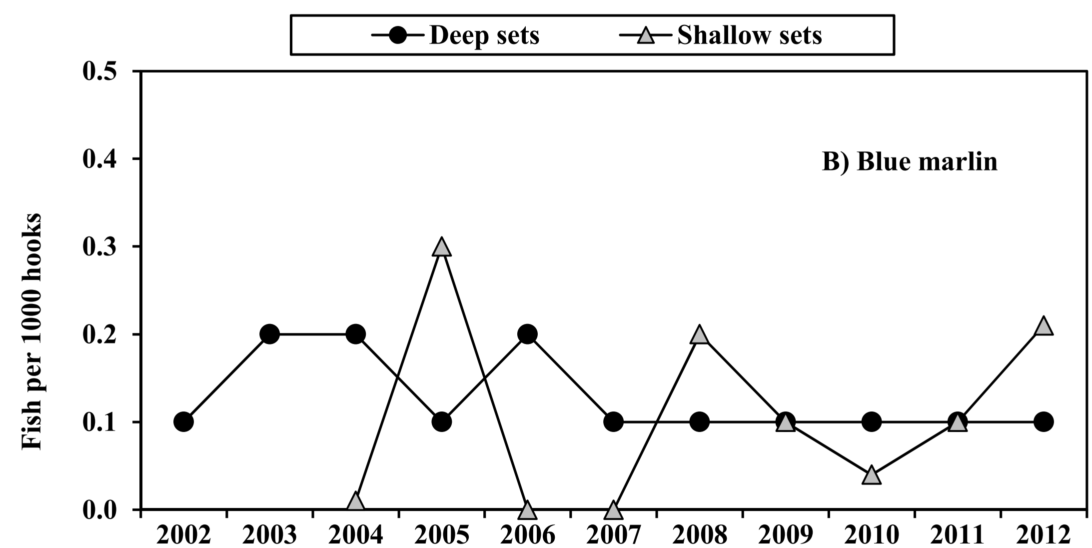

Interpretation: Striped marlin and blue marlin are caught incidentally by the longline fishery. Therefore, their catch rates are significantly lower than those for target species such as swordfish and bigeye tuna. There was little difference in striped marlin CPUE between the deep-set and shallow-set sectors. CPUE for both sectors exhibited variability with the appearance of a downward trend. Blue marlin CPUE was slightly higher in deep-set sector. The trend for in blue marlin CPUE in the deep-set sector was slightly higher through 2006, but steady throughout the 10-year period. In contrast, shallow-set CPUE for blue marlin was low but highly variable.

Source and calculation: Longline marlin CPUEs were compiled from NMFS longline logbook data and summarized based on date of haul. CPUE was based on number of marlin caught (kept + released) divided by the number of hooks set. Set type CPUE summaries were based the number of hooks between floats with a deep-set defined as a set with 15 or more hooks between floats and a shallow-set characterized by having less than 15 hooks between floats. Longline vessel operators are required to declare what set type they plan to make prior to leaving on a trip.

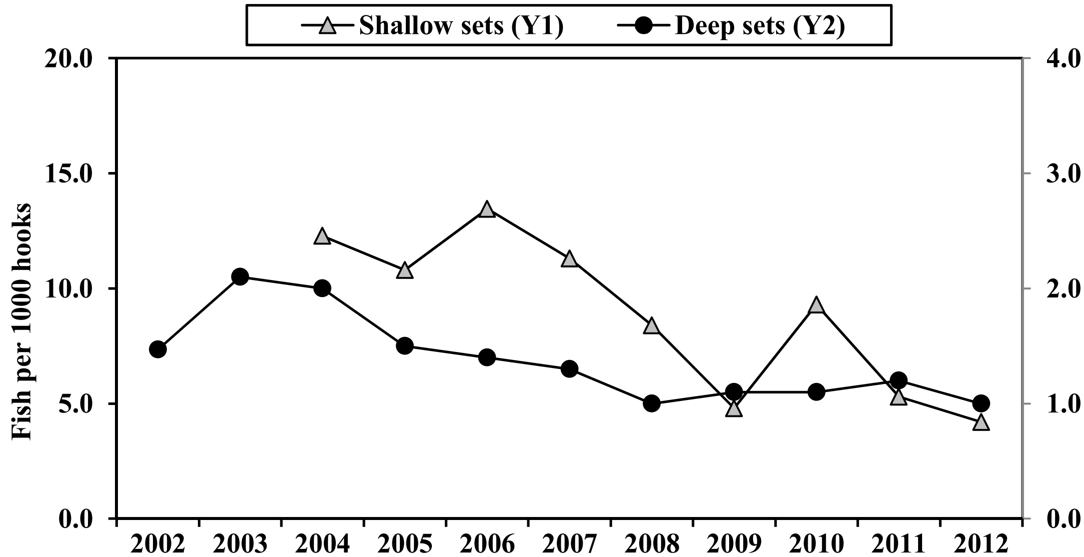
Figure 110. Hawaii longline blue shark CPUE by trip type, 2002-2012



Interpretation: Blue sharks are caught incidentally by the longline fishery. The blue shark CPUE by the shallow-set sector (Y1 axis) was more than 6-fold greater than the deep-set sector (Y2 axis). Shallow-set blue shark CPUE decreased from 13.5 in 2006 to 4.2 in 2012. Blue shark CPUE in deep-set sector declined also although at a more gradual rate.

Source and calculation: Longline blue shark CPUEs were compiled from NMFS longline logbook data and summarized based on date of haul. CPUE was based on number of sharks caught (kept + released) divided by the number of hooks set. Set type CPUE summaries were based the number of hooks between floats with a deep-set defined as a set with 15 or more hooks between floats and a shallow-set characterized by having less than 15 hooks between floats. Longline vessel operators are required to declare what set type they plan to make prior to leaving on a trip.

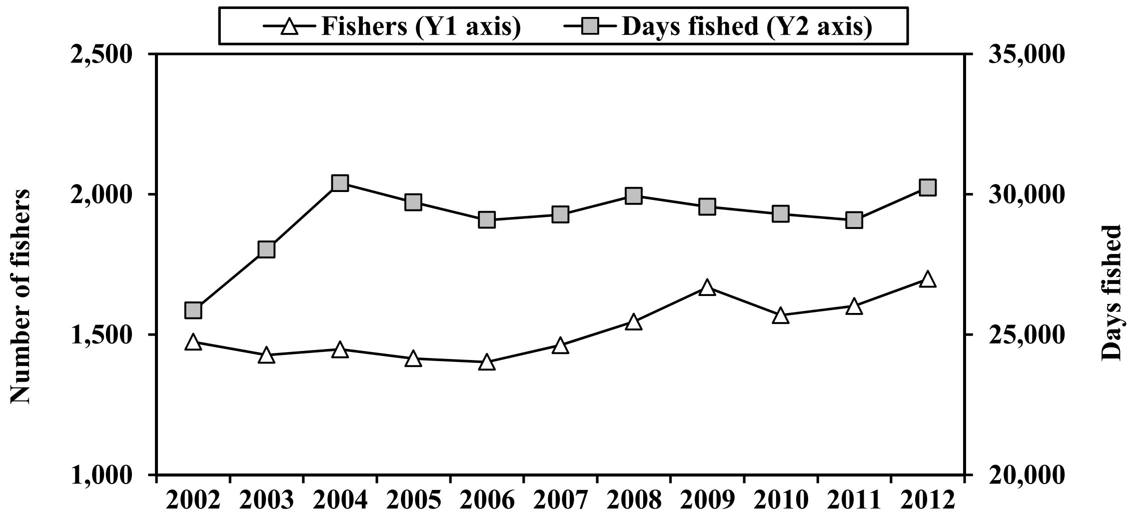
Figure 111. Number of Main Hawaiian Islands troll fishers and number of days fished, 2002-2012



Interpretation: The trend for the number of Main Hawaiian Islands (MHI) troll fishers is increasing participation. The number of fishers rose from 1,402 fishers in 2006 to a peak of 1,698 fishers in 2012. The number of days fished by the MHI troll fishery was lowest in the 2002 followed by increased effort in the following two years. Number of days fished remained steady from 2004 through 2012.

Source and calculations: The number of MHI troll fishers was based on the number of unique State of Hawaii, Division of Aquatic Resources (HDAR) issued Commercial Marine Licenses (CMLs) submitting Fishing Reports. The number of days fished by the MHI troll fishery was calculated using the Fishing Report data. A MHI troll day fished is defined as a unique CML number fishing on a unique day for the gear types and fishing in areas defined for the MHI troll fishery at the beginning of this module. The number of days fished includes days that fishers did not catch anything or days that fish were caught but not sold.

Year	Fishers	Days fished
2002	1,474	25,854
2003	1,427	28,028
2004	1,447	30,395
2005	1,415	29,714
2006	1,402	29,080

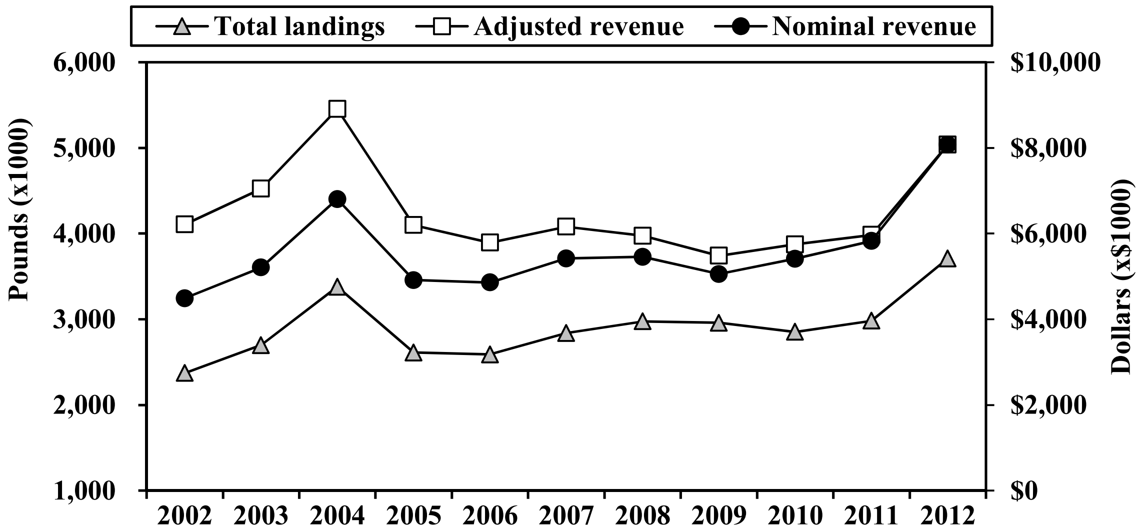
2012	1,698	30,232
Average	**1,519.1**	**29,130.5**
SD	**103.8**	**1,264.4**

Figure 112. Main Hawaiian Islands troll landings and revenue, 2002-2012



Interpretation: The total landings by the MHI troll fishery in 2012 were 3.7 million pounds worth an estimated $8.1 million. Total landings were at their highest during the ten-year period and 28% above their long-term average with a general trend increasing from 2006. Adjusted revenue peaked in 2004, remained stable from 2005 through 2011, and rose in 2012.

Source and calculations: Total landings and nominal revenue for the MHI troll fishery were derived from HDAR Commercial Fishing and Marine Dealer Report data. Total landings by the MHI troll fishery was based on a sum of Pounds Landed from the Fishing Report data or an extrapolation of Pounds Bought from the non-longline Dealer Report data. Nominal revenue is a sum of the Amount Paid from the Dealer Report data for fish caught by the MHI troll fishery. The adjusted revenue is calculated by dividing the nominal revenue by the Honolulu CPI for the respective year then multiplying the result by the current year (2012) Honolulu CPI.

Year	Total landings (1000 lbs)	Adjusted revenue ($1000)	Nominal revenue ($1000)	Honolulu CPI
2002	2,372	$6,211	$4,488	180.3
2003	2,698	$7,044	$5,209	184.5
2004	3,379	$8,907	$6,804	190.6
2005	2,612	$6,198	$4,914	197.8
2006	2,590	$5,788	$4,858	209.4
2007	2,839	$6,159	$5,418	219.5
2008	2,975	$5,947	$5,456	228.9

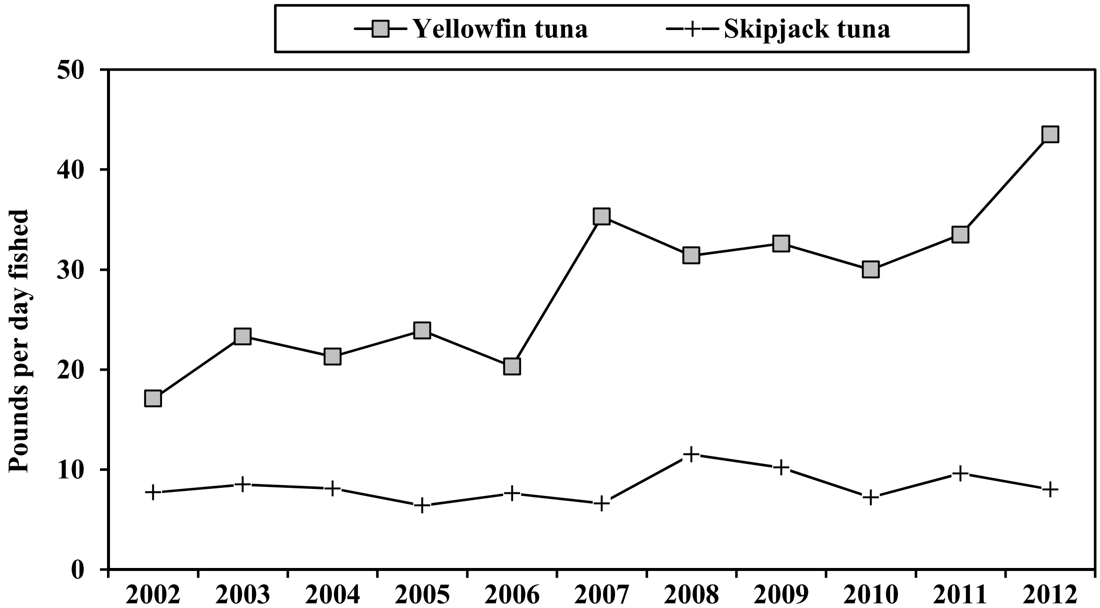
Average	**2,906.0**	**$6,502.6**	**$5,592.4**	
SD	**374.9**	**$1,075.4**	**$1,021.6**	

Figure 113. Main Hawaiian Islands troll tuna CPUE, 2002-2012



Interpretation: MHI troll yellowfin tuna CPUE was consistently higher than skipjack tuna CPUE. Yellowfin tuna CPUE was a record 44 pounds per trip in 2012 and had an increasing trend. Yellowfin tna has been above its long-term average CPUE for the past six years. Skipjack tuna CPUE was 8 pounds per trip in 2012, close to its long-term average CPUE. The trend for skipjack tuna was flat.

Source and calculations: The MHI troll CPUE values originate from HDAR Commercial Fishing Report data. CPUE based on pounds per day fished was calculated from Pounds Landed of yellowfin tuna and skipjack tuna divided by the number of MHI troll Days Fished. The number of Days Fished includes days that fishers did not catch anything or days that fish were caught but not sold. The pounds per hour fished CPUE calculation was based on the Pounds Landed divided by the sum of MHI troll Hours Fished.

MHI troll tuna CPUE (pounds per day fished)

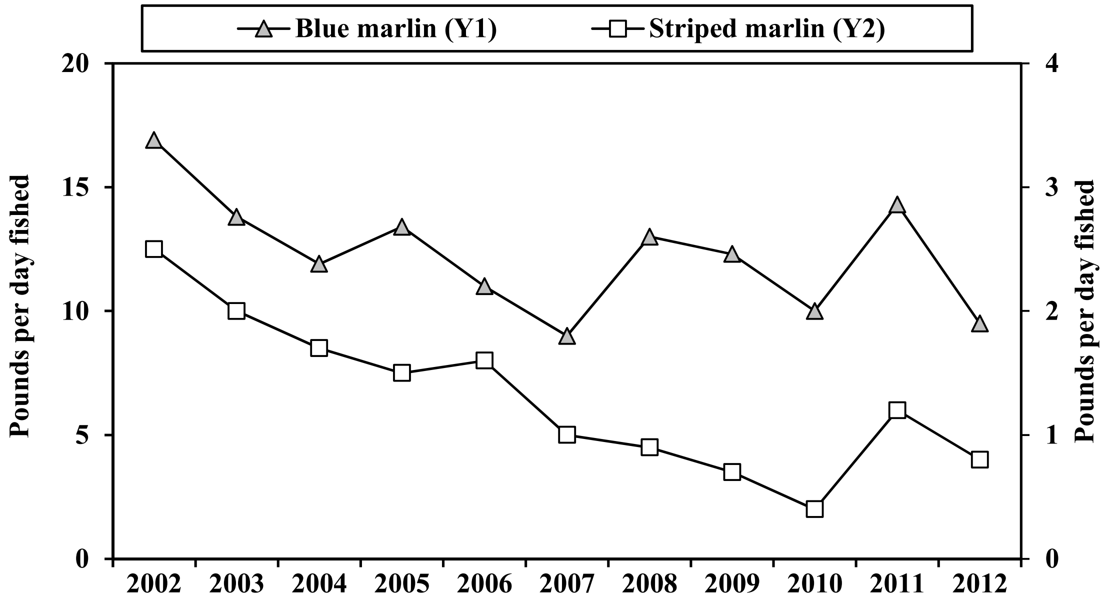
Figure 114. Main Hawaiian Islands troll marlin CPUE, 2002-2012



Interpretation: CPUE for blue marlin (Y1 axis) was substantially higher compared to the CPUE for striped marlin (Y2 axis). The CPUE trend for blue marlin was that of a decline from 2002 to a low in 2007 and somewhat variable through 2012. Striped marlin CPUE showed a longer decline from 2002 to a low in 2010. Although striped marlin CPUE was higher the following two years, the values were still below its long-term average.

Source and calculations: The MHI troll CPUE values originate from HDAR Commercial Fishing Report data. CPUE based on pounds per day fished was calculated from Pounds Landed of blue marlin and striped marlin divided by the number of MHI troll Days Fished. The number of Days Fished includes days that fishers did not catch anything or days that fish were caught but not sold. The pounds per hour fished CPUE calculation was based on the Pounds Landed divided by the sum of MHI troll Hours Fished.

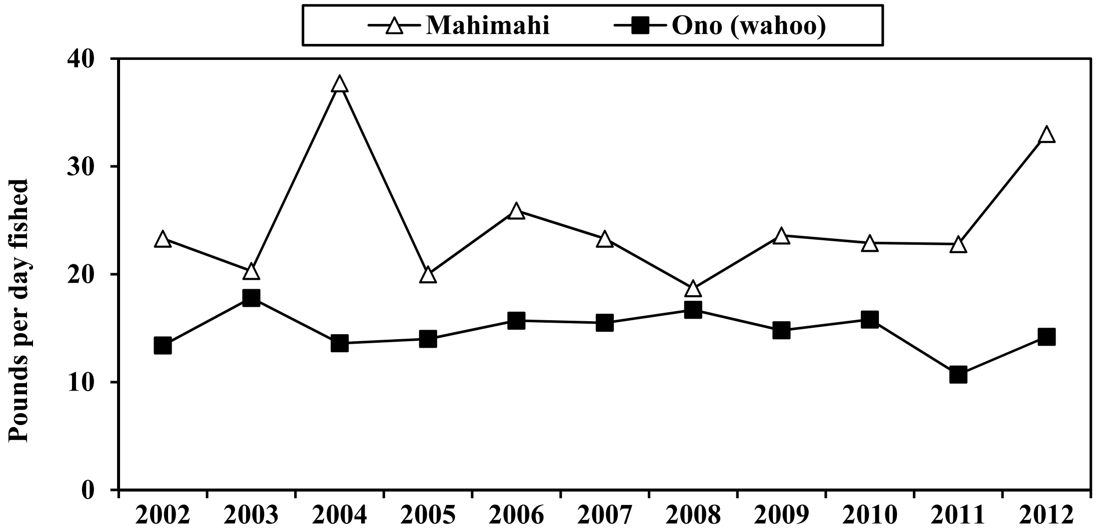
Figure 115. Main Hawaiian Islands troll mahimahi and ono CPUE, 2002-2012



Interpretation: Mahimahi CPUE for the MHI troll fishery was slightly higher and exhibited more variability than ono. Mahimahi CPUE peaked in 2004, dropped the following year, remained somewhat stable through 2011 and increased in 2012. Ono CPUE was stable from 2002 through 2010 and dropped below its long-term average in 2011 and 2012.

Source and calculations: The MHI troll CPUE values originate from HDAR Commercial Fishing Report data. CPUE based on pounds per day fished was calculated from Pounds Landed of mahimahi and ono divided by the number of MHI troll Days Fished. The number of Days Fished includes days that fishers did not catch anything or days that fish were caught but not sold. The pounds per hour fished CPUE calculation was based on the Pounds Landed divided by the sum of MHI troll Hours Fished.

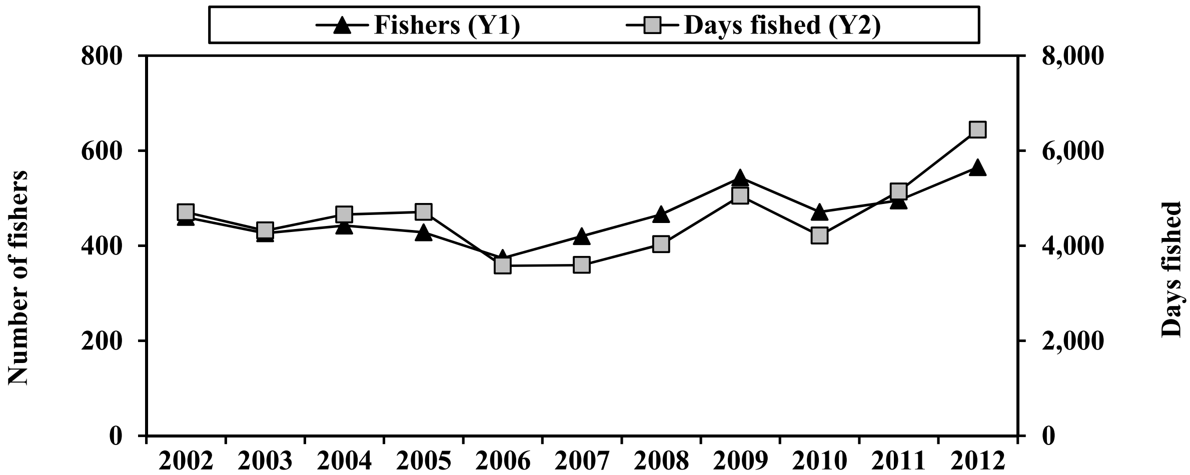
Figure 116. Number of Main Hawaiian Islands handline fishers and days fished, 2002-2012



Interpretation: There were 565 MHI handline fishers that fished 6,437 days in 2012. Both measures of effort were above their respective long-term averages. MHI handline effort was lowest in 2006 with upward trend thereafter.

Source and calculations: The number of MHI handline fishers was based on the number of unique State of Hawaii, Division of Aquatic Resources (HDAR) Commercial Marine Licenses (CMLs) submitting Fish Reports. The number of days fished by the MHI handline fishery was calculated using the HDAR Fishing Report data. A MHI handline day fished is defined as a unique CML number fishing on a unique day for the gear types and fishing in areas defined for the MHI handline fishery at the beginning of this module. The number of days fished includes days that fishers did not catch anything or days that fish were caught but not sold.

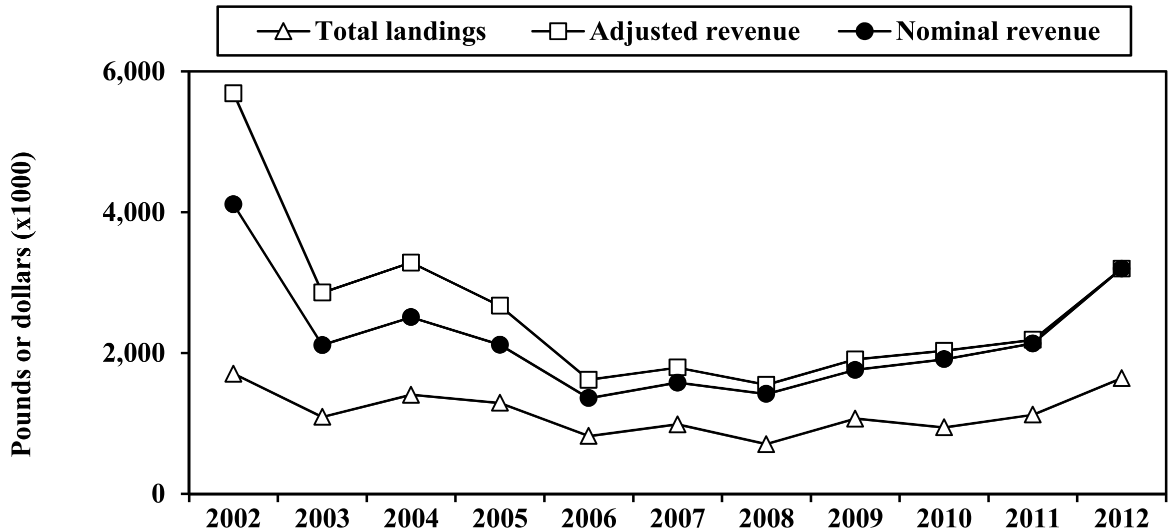
Figure 117. Main Hawaiian Island handline landings and revenue, 2002-2012

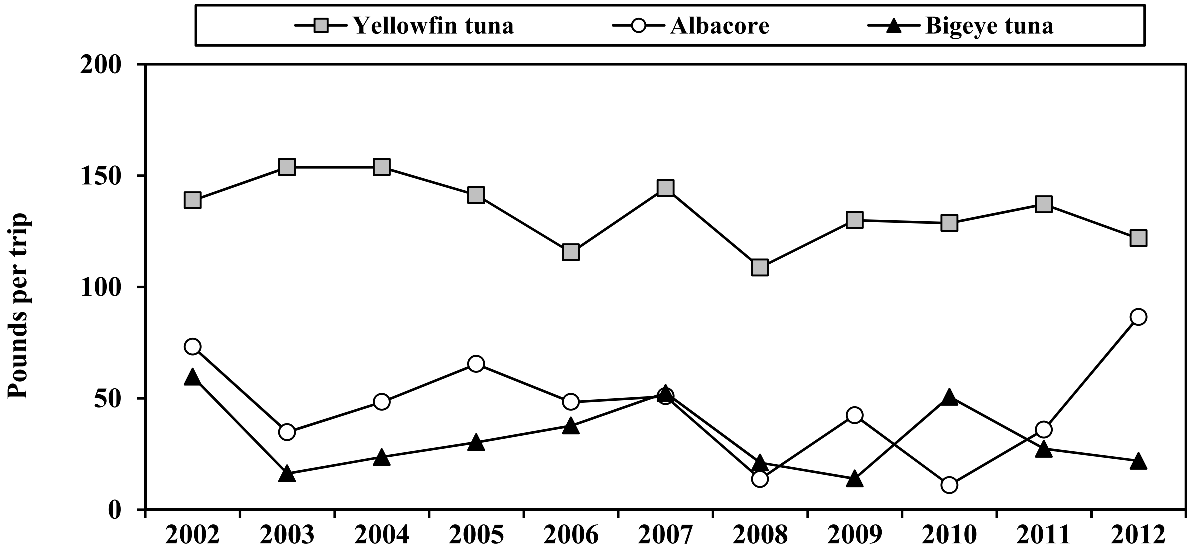


Interpretation: Total landings by the MHI handline fishery in 2012 was 1.6 million pounds, worth an estimated $3.2 million. Total landings and revenue by this fishery was above the long-term values by 41% and 22%, respectively. The recent pattern for MHI handline fishery landings and revenue was an increasing trend from 2008 through 2012.

Source and calculations: Total landings and nominal revenue for the MHI handline fishery were derived from HDAR Commercial Fishing and Marine Dealer Report data. Total landings by the MHI handline fishery was based on a sum of Pounds Landed from the Fishing Report data or an extrapolation of Pounds Bought from the non-longline Dealer Report data. Nominal revenue is a sum of the Amount Paid from the Dealer Report data for fish caught by the MHI handline fishery. The adjusted revenue is calculated by dividing the nominal revenue by the respective year Honolulu CPI and then multiplying the result by the current year (2012) Honolulu CPI.

Year	Total landings (1000 lbs)	Adjusted revenue ($1000)	Nominal revenue ($1000)	Honolulu CPI
2002	1,705	$5,687	$4,110	180.3
2003	1,092	$2,856	$2,112	184.5
2004	1,405	$3,283	$2,508	190.6
2005	1,291	$2,670	$2,117	197.8
2006	820	$1,619	$1,359	209.4
2007	984	$1,794	$1,578	219.5
2008	704	$1,546	$1,418	228.9
2009	1,066	$1,908	$1,759	230.0
2010	942	$2,030	$1,911	234.9
2011	1,124	$2,187	$2,135	243.6
2012	1,642	$3,199	$3,199	249.5
Average	1,161.4	$2,616.3	$2,200.5	
SD	319.9	$1,188.4	$821.2	

Figure 118. Main Hawaiian Island handline tuna CPUE, 2002-2012



Interpretation: MHI handline CPUE (pounds per day fished) were slightly higher than the long-term average. Yellowfin tuna was the dominant component of the handline landings and its CPUE was 122 pounds per trip in 2012; 9% below its long-term average. Nonetheless, the yellowfin tuna CPUE was relatively stable from 2002. Albacore and bigeye tuna CPUE varied substantially from 2002 with albacore CPUE reaching a peak in 2012.

Source and calculations: The MHI handline CPUE values originate from HDAR Commercial Fishing Report data. CPUE based on pounds per day fished was calculated from Pounds Landed of yellowfin tuna, albacore, and bigeye tuna divided by the number of MHI handline Days Fished. The number of Days Fished includes days that fishers did not catch anything or days that fish were caught but not sold. The pounds per hour fished CPUE calculation was based on the Pounds Landed divided by the sum of MHI handline Hours Fished. The total MHI handline CPUE also includes skipjack tuna, kawakawa, and other tunas.

	MHI handline CPUE (pounds per hour fished)			
Year	Yellowfin tuna	Albacore	Bigeye tuna	Total
2003	21.5	4.9	2.3	29.3
2004	21.5	6.8	3.3	32.8
2005	20.3	9.4	4.3	34.8

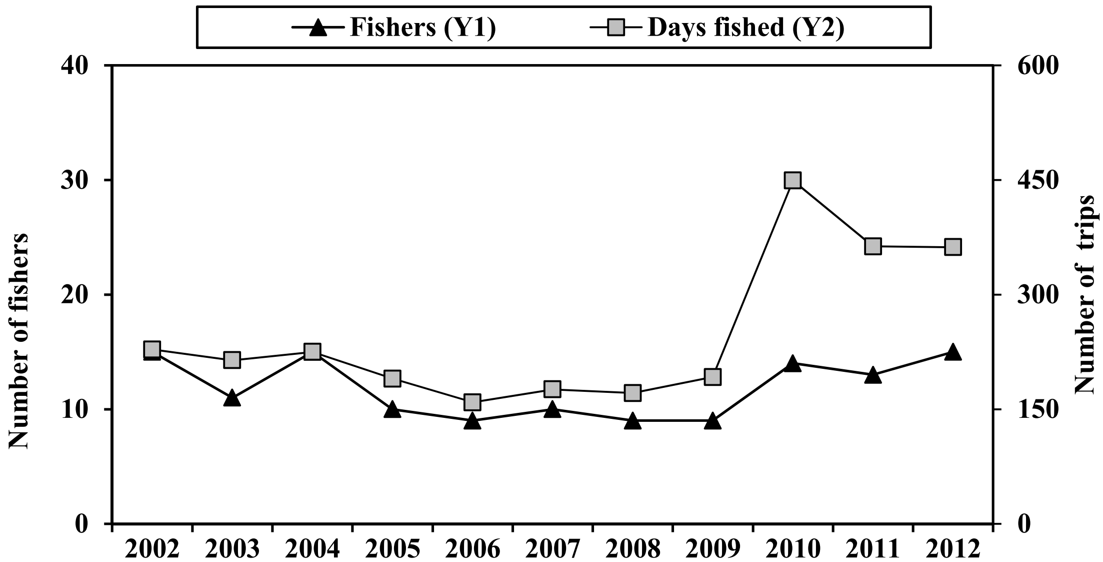
Figure 119. Number of offshore handline fishers and days fished, 2002-2012

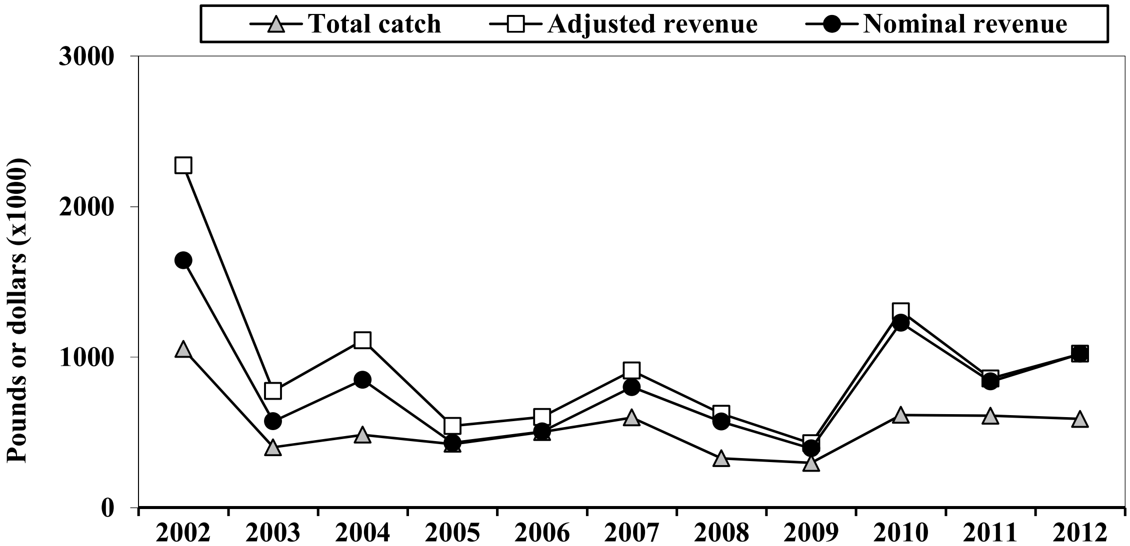


Interpretation: The offshore tuna handline fishery had 15 fishers that fished 362 days in 2012, effort close to previous. The number of fishers peaked at 15 in 2002, 2004, and 2012 with a long-term average 11.8 fishers. The number of days fished was low during 2002 through 2009 and peaked at 449 days in 2010. Days fished was nearly the same in 2011 and 2012.

Source and calculations: The number of offshore handline fishers was based on the number of unique State of Hawaii, Division of Aquatic Resources (HDAR) Commercial Marine Licenses (CMLs) submitting Fish Reports. The number of days fished by the offshore handline fishery was calculated using the HDAR Fishing Report data. An offshore handline day fished is defined as a unique CML number fishing on a unique day for the gear types and fishing in areas defined for the offshore handline fishery at the beginning of this module. The number of days fished includes days that fishers did not catch anything or days that fish were caught but not sold.

Year	Fishers	Days fished
2002	15	228
2003	11	214
2004	15	225
2005	10	190
2006	9	159
2007	10	176
2008	9	171
2009	9	192
2010	14	449
2011	13	363
2012	15	362
Average	**11.8**	**248.1**
SD	**2.6**	**97.1**

Figure 120. Offshore handline landings and revenue, 2002-2012

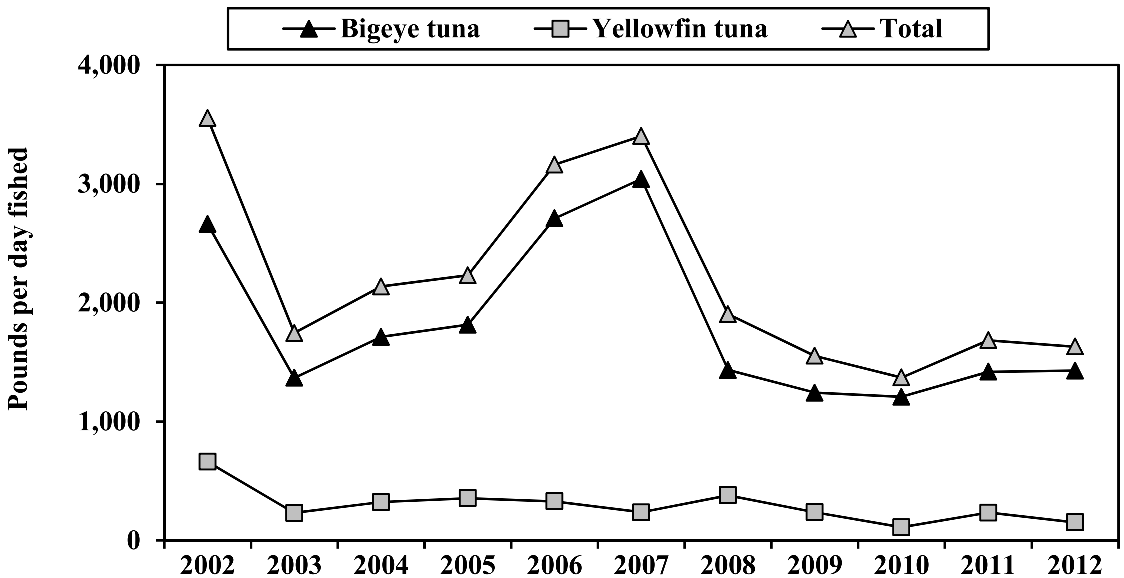


Interpretation: Total landings and revenue by the offshore handline fishery were 590,000 pounds worth an estimated $1,023 in 2012. Total landings by this fishery decreased 3% while revenue increased 19%. Both landings and revenue were above their respective long-term values in 2012. The trend for landings and revenue by the offshore handline fishery showed a steep decline from 2002 to 2003 then remaining low through 2012.

Source and calculations: Total landings and nominal revenue for the offshore handline fishery were derived from HDAR Commercial Fishing and Marine Dealer Report data. Total landings by the offshore handline fishery were based on a sum of Pounds Landed from the Fishing Report data or an extrapolation of Pounds Bought from the non-longline Dealer Report data. Nominal revenue is a sum of the Amount Paid from the Dealer Report data for fish caught by the offshore handline fishery. The adjusted revenue is calculated by dividing the nominal revenue by the respective year Honolulu CPI and then multiplying the result by the current year (2012) Honolulu CPI.

Year	Total landings (1000 lbs)	Adjusted revenue ($1000)	Nominal revenue ($1000)	Honolulu CPI
2002	1054	$2,275	$1,644	180.3
2003	402	$776	$574	184.5
2004	485	$1,113	$850	190.6
2005	424	$544	$431	197.8
2006	503	$603	$506	209.4
2007	599	$910	$801	219.5
2008	328	$623	$572	228.9
2009	298	$427	$394	230.0
2010	616	$1,305	$1,229	234.9
2011	611	$858	$838	243.6
2012	590	$1,023	$1,023	249.5
Average	**485.6**	**$818.3**	**$721.8**	
SD	**119.1**	**$276.9**	**$272.2**	

Figure 121. Offshore handline CPUE of bigeye and yellowfin tuna, 2002-2012



Interpretation: Offshore handline CPUE was 1,630 pounds in 2012, below its long-term average. CPUE for bigeye tuna and mahimahi were higher in 2012, but lower for yellowfin tuna. Since bigeye tuna is the largest component of the offshore handline fishery, its CPUE contributes to a substantial amount to the overall CPUE. In general, bigeye tuna CPUE fluctuated in the early half of the time series and has remained low from 2008. The trend for yellowfin tuna CPUE was somewhat lower in the recent part of the time series.

Source and calculations: The offshore handline CPUE values originate from HDAR Commercial Fishing Report data. CPUE based on pounds per day fished was calculated from Pounds Landed of bigeye tuna, yellowfin tuna and mahimahi divided by the number of offshore handline Days Fished. The number of Days Fished includes days that fishers did not catch anything or days that fish were caught but not sold. The pounds per hour fished CPUE calculation was based on the Pounds Landed divided by the sum of offshore handline Hours Fished. The total offshore handline CPUE also includes skipjack tuna, kawakawa, and other tunas.

	Offshore handline landings (pounds per day fished)			
Year	Bigeye tuna	Yellowfin tuna	Mahimahi	Total
2002	2,663	661	98	3,552
2003	1,367	231	61	1,744
2004	1,712	322	61	2,136
2005	1,814	355	40	2,230
2006	2,710	328	52	3,162
2007	3,041	236	34	3,402
2008	1,433	379	55	1,903
2009	1,243	238	39	1,552
2010	1,208	110	32	1,370
2011	1,418	233	18	1,684
2012	1,428	152	36	1,630
Average	**1,821.5**	**295.0**	**47.8**	**2,215.0**
SD	**662.0**	**146.9**	**21.3**	**787.2**

Table 87. Average weight by species for the troll and handline landings, 2002-2012

	Tunas				Billfish			Other PMUS	
Year	Albacore	Bigeye tuna	Skipjack tuna	Yellowfin tuna	Blue marlin	Striped marlin	Swordfish	Mahimahi	Ono (wahoo)
2002	38	30	10	42	224	42	152	16	26
2003	46	20	6	30	185	49	118	16	22
2004	43	36	6	27	207	60	142	18	23
2005	48	29	5	23	183	74	102	15	23
2006	47	27	8	29	209	69	128	16	23
2007	49	31	4	35	267	89	133	16	24
2008	51	35	6	26	205	67	158	15	26
2009	46	30	7	30	231	84	184	14	24
2010	49	32	5	30	257	107	123	14	26
2011	45	27	8	32	222	50	132	13	27
2012	49	22	5	32	270	56	126	12	25
Average	**46.4**	**29.0**	**6.4**	**30.6**	**223.6**	**67.9**	**136.2**	**15.0**	**24.4**
SD	**3.6**	**4.9**	**1.8**	**5.0**	**30.2**	**19.6**	**22.2**	**1.6**	**1.6**

Interpretation: The mean weight for albacore, skipjack tuna, yellowfin tuna, swordfish, and ono caught on troll and handline gear in 2012 was close to their respective long-term average weight. Mean weight of bigeye tuna, striped marlin and mahimahi were below their long-term mean weight. The mean weight for blue marlin was much higher in 2012 compared to its long-term average and had the biggest mean weight of all species landed by the troll and handline fishery at 270 pounds.

Source and calculations: The average weights were calculated from HDAR Commercial Marine Dealer data. The mean weight of fish was based on the total of pounds bought divided by the total number bought. Landings by the troll and handline fishery were usually landed whole. If fish were processed prior to sale, e.g., headed and gutted, gilled and gutted, a conversion factor was applied to convert it to an estimated whole weight.

E. International

Introduction

The U.S Pacific Island Exclusive Economic Zones managed by the Council are surrounded by large and diverse fisheries targeting pelagic species. The International Module contains reported catches of pelagic species in the entire Pacific Ocean by fleets of Pacific Island nations and distant water fishing nations (DWFN) and information for a Stock Assessment and Fishery Evaluation (SAFE) report that includes the most recent assessment information in relation to status determination criteria. Fishery trends in the entire Pacific Ocean are illustrated for the purse seine, longline and pole-and-line fisheries. A table lists the U.S. longline landings as submitted to the Western and Central Pacific Fisheries Commission (WCPFC) and Inter-American Tropical Tuna Commission (IATTC).

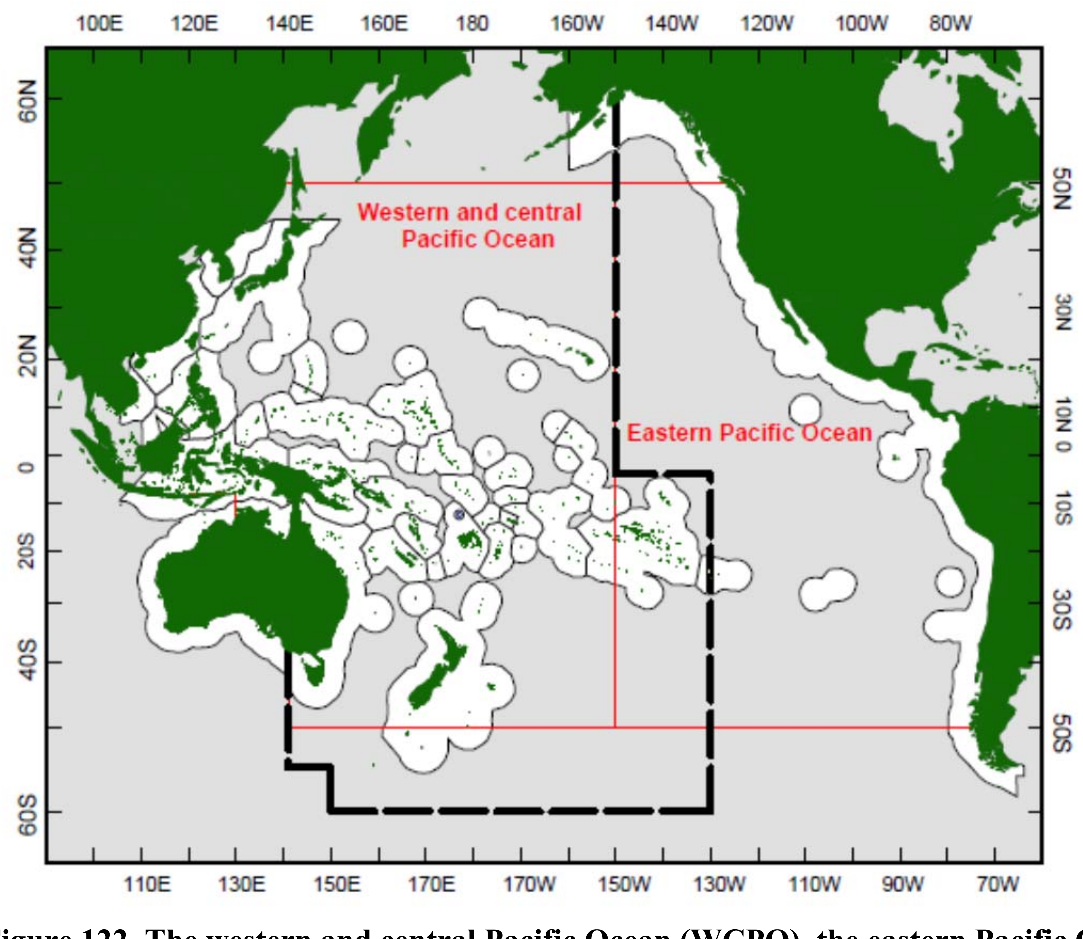


Figure 122. The western and central Pacific Ocean (WCPO), the eastern Pacific Ocean (EPO) and the WCPFC Convention Area (WCP–CA in dashed lines)

1. The 2012 purse-seine fishery in the WCPFC Convention Area (WCP-CA)
Source: WCPFC-SC8-2011 GN-WP-01

Vessels: The majority of the historic WCP–CA purse seine catch has come from the four main Distant Water Fishing Nation (DWFN) fleets – Japan, Korea, Chinese-Taipei and USA, which numbered 163 vessels in 1992, declined to a low of 111 vessels in 2006 before increasing again to 139 vessels in 2012. The Pacific Islands fleets have gradually increased in numbers over the past two decades to a level of 94 vessels in 2012. The remainder of the purse seine fishery includes several fleets which entered the WCPFC tropical fishery in the 2000s (e.g. China, Ecuador, El Salvador, New Zealand and Spain). The total number of purse seine vessels was relatively stable over the period 1990-2006 (in the range of around 180–220 vessels), but over the last five years, the number of vessels has gradually increased, attaining a level of 297 vessels in 2012.

Catch: The provisional **2012 purse-seine catch of 1,816,503 mt** was the lowest catch for five years and more than 30,000 mt higher than the record attained in 2009 (1,785,626 mt). The 2012 purse-seine skipjack catch (1,348,554 mt) was the second highest on record (after the 2009 catch) with a slight decline in the adjusted skipjack tuna catch (74%) compared to recent years. The 2012 purse-seine catch estimate for yellowfin tuna (398,464 mt – 22%) was also the second highest on record, just below the record catch of 2008 (400,908 mt) and following a relatively poor catch year in 2011. The provisional catch estimate for bigeye tuna for 2012 (69,164 mt) was again amongst the highest on record but may be revised once all observer data for 2012 have been received and processed. The high bigeye catch in 2012 coincides with the second highest number of associated sets (WCPFC Database), albeit a 15-20% reduction on the record high in 2011.

Fleet Distribution: The purse seine catch distribution in tropical areas of the WCP–CA is strongly influenced by El Nino–Southern Oscillation Index (ENSO) events. At the start of 2006, a weak La Niña-state presided, but soon dissipated and a weak El Niño event then presided over the remainder of 2006. During the first half of 2007, the WCP–CA was in an ENSO-neutral state, but then moved into a prolonged La Niña state, which persisted throughout 2008 and into 2009. There was a transition in the middle of 2009 to an El Niño period which then presided into the first quarter of 2010. Conditions in the WCP-CA then switched back to a strong La Niña state over the latter months of 2010 and into the first half of 2011. It weakened, and then strengthened toward the end of 2011. The beginning of 2012 experienced a return to neutral ENSO conditions and other than relatively weak El Nino-type readings in the middle of the year, 2012 was essentially characterized as a neutral ENSO period. In line with the prevailing ENSO conditions, fishing activity during 2012 extended further east than previous years, particularly compared to 2011 which began with a strong La Niña and effort concentrated in the western regions of the tropical WCPO (i.e. the waters of the PNG, FSM and Solomon Islands).

Table 88. Total reported purse seine catch (metric tonnes) of skipjack, yellowfin and bigeye tuna in the Pacific Ocean, 1993-2012

Year	Skipjack	Yellowfin	Bigeye	Total
1993	688,201	444,283	44,040	1,176,524

2. The 2012 longline fishery in the WCP-CA
Source: WCPFC-SC8-2011 GN-WP-01

Vessels: The total number of vessels involved in the fishery has generally fluctuated between 3,000 and 6,000 for the last 30 years. The fishery involves two main types of operation:

- **Large** (typically >250 GRT) **distant-water** freezer vessels which undertake long voyages (months) and operate over large areas of the region. These vessels may target either tropical (yellowfin, bigeye tuna) or subtropical (albacore tuna) species.
- **Smaller** (typically <100 GRT) **offshore** vessels which are usually **domestically-based**, undertaking trips less than one month, with ice or chill capacity, and serving fresh or air-freight sashimi markets, or albacore canneries.

The following broad categories of longline fishery, based on type of operation, area fished and target species, are currently active in the WCP–CA:

- **South Pacific offshore albacore fishery** comprises Pacific-Islands domestic "offshore" vessels, such as those from American Samoa, Cook Islands, Fiji, French Polynesia, New Caledonia, Samoa, Solomon Islands, Tonga and Vanuatu; these fleets mainly operate in subtropical waters, with albacore the main species taken. Two new entrants, Tuvalu and Wallis& Futuna, joined this category during 2011.
- **Tropical offshore bigeye/yellowfin-target fishery** includes "offshore" sashimi longliners from Chinese-Taipei based in Micronesia, Guam, Philippines and Chinese-Taipei; mainland Chinese vessels based in Micronesia; and domestic fleets based in Indonesia, Micronesian countries, Philippines, PNG, the Solomon Islands and Vietnam.
- **Tropical distant-water bigeye/yellowfin-target fishery** comprises "distant-water" vessels from Japan, Korea, Chinese-Taipei, mainland China and Vanuatu. These vessels primarily operate in the eastern tropical waters of the WCP–CA, targeting bigeye and yellowfin tuna for the frozen sashimi market. The Portuguese fleet (one vessel) started fishing in 2011.
- **South Pacific distant-water albacore fishery** comprises "distant-water" vessels from Chinese-Taipei, mainland China and Vanuatu operating in the south Pacific, generally below 20°S, targeting albacore tuna destined for canneries.
- **Domestic fisheries in the sub-tropical and temperate WCP–CA** comprise vessels targeting different species within the same fleet depending on market, season and/or area. These fleets include the domestic fisheries of Australia, Japan, New Zealand and Hawaii. For example, the Hawaii longline fleet has a component that targets swordfish and another that targets bigeye tuna.
- **South Pacific distant-water swordfish fishery** is a relatively new fishery and comprises "distant-water" vessels from Spain.
- **North Pacific distant-water albacore and swordfish fisheries** mainly comprise "distant-water" vessels from Japan (swordfish and albacore), Chinese-Taipei (albacore only) and Vanuatu (albacore only).

Catch: The provisional WCP–CA longline catch (262,076 mt) for 2012 was the fifth highest on record, at around 15,000 mt lower than the highest on record attained in 2009 (279,012 mt). The WCP–CA albacore longline catch (98,854 mt – 37%) for 2012 was the third highest on record, 4,000 mt lower than the record (103,364 mt in 2010). The provisional bigeye catch (76,599 mt –

29%) for 2012 was similar to the level in 2011 which is below the average for the past ten years. The yellowfin catch for 2012 (85,245 mt – 32%) was the lowest for four years but similar to the average catch level for this species over the past decade.

A significant change in the WCP–CA longline fishery over the past 10 years has been the growth of the Pacific Islands domestic albacore fishery, which has risen from taking 33% of the total south Pacific albacore longline catch in 1998 to accounting for around 50-60% of the catch in recent years. The combined national fleets (including chartered vessels) mainly active in the Pacific Islands domestic albacore fishery have numbered more than 500 (mainly small "offshore") vessels in recent years and catches are now at a similar level as the distant-water longline vessels active in the WCP–CA.

The distant-water fleet dynamics continue to evolve in recent years, with catches down from record levels in the mid-2000s initially due to a reduction in vessel numbers, although vessel numbers for some fleets appear to be on the rise again in recent years, but with variations in areas fished and target species. The Japanese distant-water and offshore longline fleets have experienced a substantial decline in both bigeye catches (from 20,725 mt in 2004 to 7,683 mt in 2012) and vessel numbers (366 in 2004 to 124 in 2012). The Chinese-Taipei distant-water longline fleet bigeye catch declined from 16,888 mt in 2004 to 7,503 mt (in 2012), mainly related to a substantial drop in vessel numbers (137 vessels in 2004 reduced to 87 vessels in 2009). The Korean distant-water longline fleet experienced smaller declines in bigeye and yellowfin catches in recent years, but with a more significant drop in vessel numbers – from 184 vessels active in 2002 reduced to 108 vessels in 2008, but back to 126 vessels in 2012.

Fleet Distribution: Effort by the **large-vessel, distant-water fleets** of Japan, Korea and Chinese-Taipei account for most of the effort but there has been some reduction in vessel numbers in some fleets over the past decade. Effort is widespread as sectors of these fleets target bigeye and yellowfin for the frozen sashimi market in central and eastern tropical waters, and albacore for canning in the more temperate waters. Activity by the **foreign-offshore fleets** from Japan, mainland China and Chinese-Taipei is restricted to tropical waters, targeting bigeye and yellowfin for the fresh sashimi market; these fleets have limited overlap with the distant-water fleets. The substantial "**offshore**" effort in the west of the region is primarily by the Indonesian and Chinese-Taipei **domestic fleets** targeting yellowfin and bigeye. The growth in **domestic fleets** in the South Pacific over the past decade has been noted; the most prominent examples are the increases in the Samoan, Fijian and French Polynesian fleets, and more recently the Solomon Islands chartered vessels.

3. The 2012 pole-and-line fishery in the WCP-CA
Source: WCPFC-SC8-2011 GN-WP-01

Vessels: The pole-and-line fleet was composed of less than 200 vessels in the 2012 fishery which excludes vessels in the Indonesia domestic fishery.

Catch: The 2012 pole-and-line catch (224,207 mt) was the lowest annual catch since the late-1960s and continuing the trend in declining catches for three decades. Skipjack tends to account for the majority of the catch (~70-83% in recent years, but typically more than 85% of the total catch in tropical areas) and albacore (8–20% in recent years) is taken by the Japanese coastal and offshore fleets in the temperate waters of the north Pacific. Yellowfin tuna (5–16%) and a small component of bigeye tuna (1–4%) make up the remainder of the catch. The Japanese distant-water and offshore fleets (78,838 mt in 2012), and the Indonesian fleets (133,306 mt in 2012), account for most of the WCP–CA pole-and-line catch. The catches by the Japanese distant-water and offshore fleets in recent years have been the lowest for several decades and this is no doubt related to the continued reduction in vessel numbers (in 2012 reduced to only 90 vessels, the lowest on record). The Solomon Islands fleet recovered from low catch levels experienced in the early 2000s (only 2,773 mt in 2000 due to civil unrest) to reach a level of 10,448 mt in 2003. This fleet ceased operating in 2009, but resumed fishing in 2011 and took 11,221 mt in 2012, the highest catch since 1999.

Fleet Distribution: The WCP–CA pole-and-line fishery has several components:

- The year-round tropical skipjack fishery, mainly involving the domestic fleets of Indonesia, Solomon Islands and French Polynesia, and the distant water fleet of Japan;
- Seasonal sub-tropical skipjack fisheries in the home waters of Japan, Australia, Hawaii and Fiji;
- A seasonal albacore/skipjack fishery east of Japan (largely an extension of the Japan home-water fishery).

F. Marine Recreational Fisheries of the Western Pacific Region

Introduction

Fishing, either for subsistence or recreation, continues to be an important activity throughout the Western Pacific Region in the four major populated island areas of the Western Pacific Region, Hawaii, American Samoa, Guam and the Commonwealth of the Northern Mariana Islands (CNMI). Fish consumption in Micronesia and Polynesia typically averages about 130 lb/per capita/yr (Dalzell et al. 1996) and even in more culturally diverse Hawaii, fish consumption is almost three times the US national average at about 42 lb/person/yr (Dalzell & Paty 1996).

Recreational fisheries in the Western Pacific Region

In Hawaii, recreational shoreline fishing was more popular than boat fishing up to and after WW II. Boat fishing during this period referred primarily to fishing from traditional canoes (Glazier 1999). All fishing was greatly constrained during WW II through time and area restrictions, which effectively stopped commercial fishing and confined recreational fishing to inshore areas (Brock 1947). Following WWII, the advent of better fishing equipment and new small boat hulls and marine inboard and outboard engines led to a growth in small vessel-based recreational fishing.

A major period of expansion of small vessel recreational fishing occurred between the late 1950s and early 1970s, through the introduction of fiberglass technology to Hawaii and the further refinement of marine inboard and outboard engines (Figure 154). By the early 1960s, there were an estimated 5,300 small boats in the territory being used for recreational fishing. By the 1980s, the number of recreational or pleasure craft had risen to almost 13,000 vessels and to about 15,000 vessels in the 1990s. There are presently about 30 fishing clubs in Hawaii and a variety of different recreational fishing tournaments organized both by clubs and independent tournament organizers. Hawaii also hosts between 150 and 200 boat-based fishing tournaments, about 30 of which are considered major international competitions, with over 20 boats and entry fees of $100. This level of interest in recreational fishing is sufficient to support a local fishing magazine, Hawaii Fishing News, which besides articles of interest to recreational fishermen, includes a monthly roundup of the fishing activity and conditions at the major small boat harbors in the State.

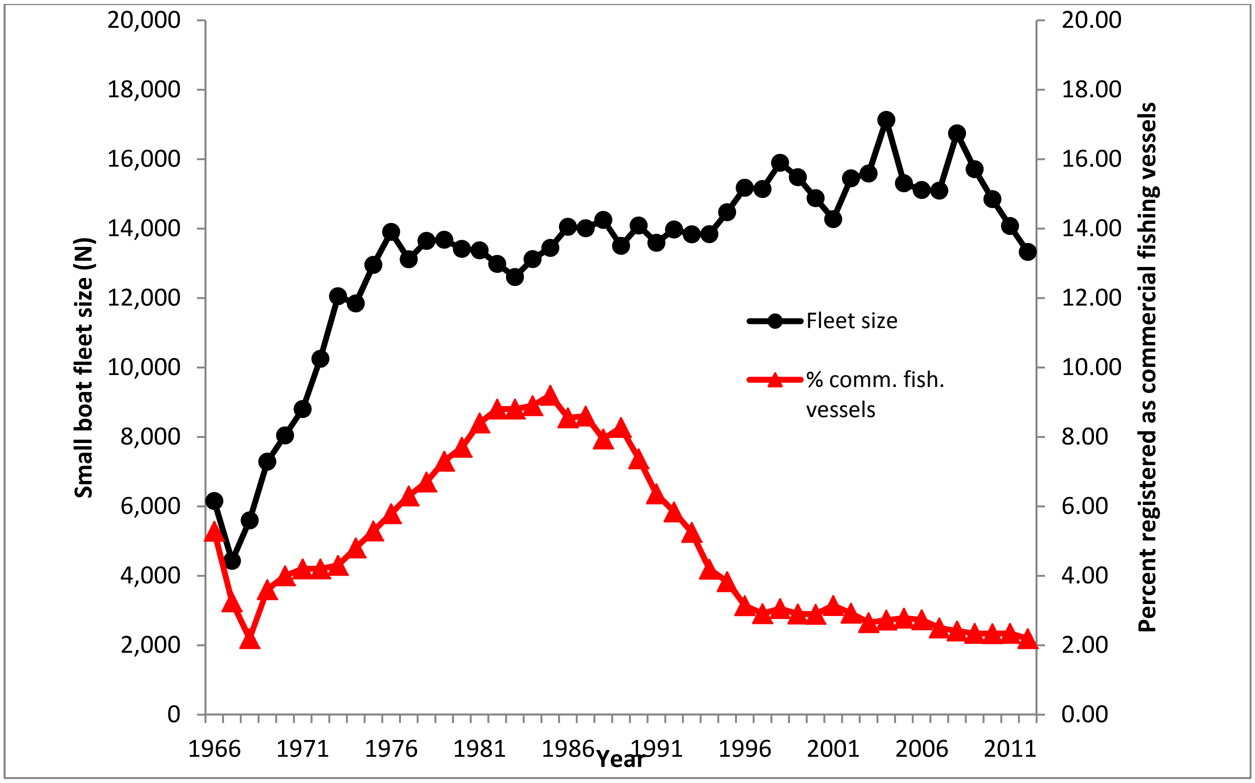

Figure 128. Annual number of small vessel fleet registrations in Hawaii, 1966-2012 - total fleet size and percentage of vessels being registered for commercial fishing
(Source: Hawaii Division of Boating and Ocean Resources)

Elsewhere in the region, recreational fishing is less structured. In Guam, fishing clubs have been founded along ethnic lines by Japanese and Korean residents. These clubs had memberships of 10-15 people, along with their families. Four such clubs were founded in Guam during the past 20 years, but none lasted for more than a 2-3 years (Gerry Davis, NMFS PIRO pers. comm.). There was also a Guam Boating Association comprising mostly fishermen, with several hundred members. This organization functioned as a fishing club for about 10 years and then disbanded. Some school groups and the Boy Scouts have formed fishing clubs focused on rod and reel fishing, and there is still one spear-fishing club that has only a handful of members, but appears to still be active. There are also some limited fishing tournaments on Guam, including a fishing derby for children organized by the local Aquatic and Wildlife Resources Division. There are few fishing clubs in the in the Northern Mariana Islands. The Saipan Sportfishing Association (SSA) has been in existence for at least 16 years, and is the sponsor of the annual Saipan International Fishing Tournament, which is usually held in August or September. In 1997, the SSA listed approximately 40 members. A recent innovation in the Mariana Island is the publication of a free quarterly magazine, Mariana Fishing Magazine, which covers recreational fishing in both Guam and the CNMI.

Levine and Allen (2009) provide an overview of fisheries in American Samoa, including subsistence and recreational fisheries. Citing a survey conducted in American Samoa by Kilarski *et al.* (2006), Levine and Allen noted that approximately half of the respondents stated that they fished for recreation, with 71 percent of these individuals fishing once a week or less. Fishermen also fished infrequently for cultural purposes, although cultural, subsistence, and recreational fishing categories were difficult to distinguish as one fishing outing could be motivated by all three reasons.

Boat-based recreational fishing in American Samoa has been influenced primarily by the fortunes of fishing clubs and fishing tournaments. Tournament fishing for pelagic species began in American Samoa in the 1970s, and between 1974 and 1998, a total of 64 fishing tournaments were held in American Samoa (Tulafono 2001). Most of the boats that participated were alia catamarans and small skiffs. Catches from tournaments were often sold, as most of the entrants are local small-scale commercial fishermen. In 1996, three days of tournament fishing contributed about one percent of the total domestic landings. Typically, 7 to 14 local boats carrying a total of 55 to 70 fishermen participated in each tournament, which were held two to five times per year (Craig et al. 1993).

The majority of tournament participants operated 28-foot alia, the same vessels that engage in the small-scale longline fishery. With more emphasis on commercial longline fishing since 1996, interest in the tournaments waned (Tulafono 2001) and pelagic fishing effort shifted markedly from trolling to longlining. Catch-and-release recreational fishing is virtually unknown in American Samoa. Landing fish to meet cultural obligations is so important that releasing fish would generally be considered a failure to meet these obligations (Tulafono 2001). Nevertheless, some pelagic fishermen who fish for subsistence release fish that are surplus to their subsistence needs.

More recently, recreational fishing has undergone a renaissance in American Samoa through the establishment of the Pago Pago Game Fishing Association (PPGFA), which was founded by a group of recreational anglers in 20032. The motivation to form the PPGFA was the desire to host regular fishing competitions. There are about 15 recreational fishing vessels ranging from 10 ft single engine dinghies to 35 ft twin diesel engine cabin cruisers. The PPGFA has annually hosted international tournaments in each of the past five years with fishermen from neighboring Samoa and Cook Islands attending. The recreational vessels use anchored fish aggregating devices (FADs) extensively, and on tournaments venture to the various outer banks which include the South Bank (35 miles), North East Bank (40 miles NE), South East bank (37 miles SE), Two Percent Bank (40 miles), and East Bank (24 miles East). Several recreational fishermen have aspirations to become charter vessels and are in the process of obtaining captains (6 pack) licenses. In 2011, PPGFA played host to the 12th Steinlager I'a Lapo'a Game Fishing Tournament, which was a qualifying event for the International Game Fish Association’s Offshore World Championship in Cabo San Lucas, Mexico.

There is no full-time regular charter fishery in American Samoa similar to those in Hawaii or Guam. However, Pago Pago Marine Charters3, which is concerned primarily with industrial

---

2 http://ppgfa.com/page/about-ppgfa

3 http://pagopagomarinecharters.com/

work such as underwater welding, construction, and salvage, also includes for-hire fishing among the services it offers.

There is also some recreational fishing activity at some of the Pacific Remote Island Areas (PRIAs), namely at Midway, Wake and Palmyra Islands. There are no resident populations at Howland & Baker, Johnston and Jarvis Islands and fishing activity at these locations is likely minimal. There was a tourist facility at Midway until 2002, which operated a charter boat fishery targeting primarily pelagic fish at Midway Atoll. The company operated five vessels for charter fishing at Midway: three 22-26 ft catamarans for lagoon and nearshore fishing operations and two 38 ft sportfishing vessels used for blue water trolling. In addition, there were approximately seven small vessels maintained and used by Midway residents for recreational fishing. Of this total, three vessels engaged primarily in offshore trolling for PMUS including yellowfin tuna, whaoo and marlin. All vessels fishing at Midway were required to file a float plan prior to a fishing trip and complete the “Midway Sports Fishing Boat Trip Log” upon completion of each trip. The US Fish and Wildlife Service was responsible for compiling these catch data.

At Palmyra Atoll, an island privately owned by The Nature Conservancy, a 22 ft catamaran is used for offshore trolling and four small boats operated within the lagoon used for bonefish angling. There are several craft used for recreational fishing at the military base on Wake Island including two landing craft and two small vessels.

Recreational catches
Estimates of recreational pelagic fish catch for the Western Pacific are given in Table 133. The data for Guam, CNMI, and American Samoa are based on the proportion of catches landed for sale and catches retained and not sold, in all landings sampled by creel surveys in each area. The ratio of unsold to sold catch in the samples was used in conjunction with the total catch estimate expanded from the creel survey data. This was adjusted downwards based on the creel surveys by the ratio of landings by vessels retaining 100% of their catch to the total unsold catch. This accounts for that fraction of the catch not sold by commercial fishing vessels. The volume of fish landed by vessels retaining all their catch was labeled the nominal recreational catch.

The estimates for American Samoa are almost certainly under-estimates due to the creel surveys not picking up the activities of sports-fishermen belonging to the Pago Pago Yacht Club. Most of their activities are conducted on the weekend, when the creel survey mounted by DMWR is inactive. A special survey is being undertaken by DMWR staff to capture this recreational fishing activity.

The recreational catch for Hawaii is generated from the Hawaii Marine Recreational Fisheries Statistical Survey, which is a collaborative effort between the State of Hawaii’s Division of Aquatic Resources and the National Marine Fisheries Service (NMFS) Office of Science and Technology. This survey is part of the NMFS Marine Fisheries Recreational Statistical Survey (MRFSS) which has been modified following a review by the National Academy of Science in 2006 under the auspices of the Marine Recreational Improvement Program (MRIP).

Table 95. Estimated boat-based recreational pelagic fish catches in the four principal island groups of the Western Pacific Region in 2012

Location	Total catch (lbs)	Unsold catch (lb)	Nominal recreational catch (lb)	Recr. catch as % of total catch	Recr. fishing trips
American Samoa	8,863,848	2,753	2,253	0.025%	4
Guam	233,829	115,792	83,487	35.7%	4,119
Hawaii	44,436,638	NA	12,330,638	27.75%	324,593
CNMI	178,438	18,218	18,030	10.10%	1,911

Charter vessel sports-fishing

Tables 96-99 present summaries of the charter vessel sportsfishing in the Western Pacific. Charter fishing in Hawaii is more focused on catching blue marlin, which in 2004 formed about 50 % of the total annual charter vessel catch by weight, but in 2012 only formed about 20% of the charter vessel catch and was superseded by yellowfin and mahmahi. Although commercial troll vessels take blue marlin, this species only forms about 6% of their catch, with the majority of the target species being yellowfin, mahimahi, and wahoo (Table 97). Unlike other parts of the US, there is little recreational fishery interest in catching sharks in Hawaii.

Guam has a charter fishing sector, which unlike Hawaii, caters for both pelagic and bottomfish fishing. Until recently, the troll charter fishery was expanding, but over the past few years, the number of vessels involved and level of fishing has decreased in response to lower tourist volume from Japan due to the ongoing economic recession. Nonetheless, although compromising about 5% of Guam's commercial troll fleet, the Guam troll charter industry accounts for 8.4% of the troll catch, and 36% and 13% of the Guam blue marlin and mahimahi catch respectively (see Guam module in this volume).

Charter fishing in CNMI is limited, with about ten boats operating on Saipan, and a few vessels on Tinian conducting occasional fishing charters. In American Samoa, tourism is not a significant component of the economy, and hence there is little charter fishing activity. As noted previously, there are few vessels suitable for charter-type operations (Tulafono 2001).

Table 96. Estimated catches by pelagic charter fishing vessels in Guam, Hawaii and CNMI in 2012

Location	Catch (lb)	Effort (trips)	CPUE (lb/trip)	Principal species
Guam	38,639	983	39.3	Mahimahi, Blue marlin, Skipjack
Hawaii	661,477	9,324	70.9	Yellowfin, Mahimahi, Blue marlin
CNMI	4,922	173	28.5	Wahoo, Skipjack, Mahimahi

Charter vessel fishing in the Western Pacific Region has elements of both recreational and commercial fishing. The primary motivation for charter patrons is recreational fishing, with the possibility of catching large game fish such as blue marlin. The charter vessel skipper and crew receive compensation in the form of the patron's fee, but are also able to dispose of fish on local markets, as is the case in Hawaii. The catch composition of charter vessel catch versus conventional commercial trolling in Hawaii reflects the different targeting in the two fisheries. Blue marlins are among the dominant catch of charter vessels in Hawaii (Table 97), along with yellowfin and mahimahi. In Guam, blue marlin are also a dominant feature in charter catches, though the single largest catch is mahimahi (Table 98). In the CNMI, blue marlin are rarely taken by the charter fishery and catches are dominated by wahoo, mahimahi and skipjack (Table 99).

Table 97. Comparison of species composition of landings made by Hawaii pelagic charter vessels versus commercial troll vessels, 2012

In Hawaii there is considerable variation in charter vessel catches between the various islands (Table 100), with the largest charter vessel fishery based on the island of Hawaii. However, in 2012, charter vessel catches on the island of Oahu accounted for 33.5% of the total charter vessel landings within the state, with the Hawaii charter catch being slightly smaller at about 31% of the total.

Table 100. Charter vessel catches in Hawaii by island, 2012

Island	Catch (lb)	Percent	Trips	Percent	CPUE (lb/trip)
Hawaii	202,775	30.65%	4,013	43.04%	50.53

Oahu	221,232	33.45%	2,082	22.33%	106.26
Total	**661,477**	**100.00%**	**9,324**	**100.00%**	**70.94**

* DAR confidentiality protocols prevent reporting charter vessel activity for Molokai and Lanai separately, and these are aggregated with data for Maui, reported collectively as Maui County

Most charter vessel fishing on the island of Hawaii is conducted from Kona's small boat harbor at Honokohau, and about 36% of the charter vessel catch is comprised of blue marlin (Table 101). Blue marlin used to amount to about two-thirds of the catch, but this number has fallen considerably with the spread of a stronger catch and release ethic for billfish by charter vessel operators at Honokohau. Elsewhere, yellowfin, mahimahi and wahoo tend to dominate charter vessel landings.

Table 101. Composition of charter vessel catches in the Main Hawaiian Islands, 2012

Hawaii	Landings (lb)	Percent	Kauai	Landings (lb)	Percent

Recreational Fishing Data Collection in Hawaii

Recreational fish catches in Hawaii are monitored through the Hawaii Marine Recreational Fishing Survey (HMRFS), a collaborative project of the NMFS Office of Science and Technology and the Hawaii Division of Aquatic Resources. This project is a segment of the nationwide Marine Recreational Fisheries Statistical Survey (MRFSS), which has been used by NMFS to estimate recreational catches in most of the coastal states of the US.

The MRFSS program uses a triple survey approach that has been developed over the 20+ years of its history. For each two-month survey period (wave) a random sample of households is called by telephone to determine how many have conducted any fishing in the ocean, their mode of fishing (private boat, rental boat, charter boat, or shoreline), what methods were used, and how much effort (number of trips and hours) was expended. Concurrently, surveyors are sent out to boat launch ramps, small boat harbors, and shoreline fishing sites to interview fishermen to fill out intercept survey forms. The intercept survey collects data on fishing area, fishing methods, trip/effort, species caught, and lengths and weights of fish. The sites are randomly selected, but stratified by fishing pressure so that the sites with the highest pressures are likely to be surveyed more often. In addition the charter boat operators are surveyed by a separate survey. This additional survey of the charter fleet serves the same function as the random digit dialing household survey and is necessary because out of town fishers that charter vessels would not be covered by randomly calling the Hawaiian populace. The telephone and charter survey data are used to estimate total statewide fishing effort and the intercept surveys provide detailed catch and trip information. Data from the three surveys are combined and expanded to yield statewide estimates of total effort and catch by species, mode, and county.

NMFS and HDAR contributed joint funding for intercept surveys and charter boat surveys on the islands of Oahu, Hawaii, and Maui. NMFS also funded the Random Digit Dialing household telephone survey via a national contractor beginning in January 2001. The HMRFS project commenced in July 2001 but took until 2003 until annual results were first reported from this initiative.

In 2006, the MRFSS survey was reviewed by the National Research Council of the National Academy of Sciences (NRC 2006). The reviewers were critical of the statistical methods employed to generate expansions of the survey data to annual recreational catch estimates for each state. Consequently, NMFS conducted an overhaul of the MRFSS survey to respond to the NRC criticisms. As such, readers of this report should understand that there is uncertainty surrounding the various expansions from the HMRFS survey and figures reported here may change as new methods are implemented to conduct the expansions from survey data.

Table 102 provides summaries of the recreational boat and shoreline fish catch between 2003 and 2012 for pelagic fish.

Table 102. Recreational pelagic fish catches in Hawaii between 2003 and 2012

Year	Shore catch (lb)	Vessel catch (lb)	Total (lb)
2003	422,439	14,906,148	15,328,587
2004	120,779	12,210,682	12,331,461
2005	229,059	11,564,698	11,793,758
2006	258,802	11,830,852	12,089,654
2007	114,832	13,956,644	14,071,475
2008	56,937	21,802,388	21,859,325
2009	66,635	17,071,414	17,138,049
2010	14,469	11,754,054	11,768,523
2011	14,216	10,574,696	10,588,912
2012	NA	12,330,638	12,330,638

Source: HDAR HMFRS and NMFS PIFSC

Figures 129-132 summarize aspects of the boat-based recreational fishery landings for six major pelagic fish species in Hawaii (blue marlin, striped marlin, mahimahi, skipjack, yellowfin and wahoo) between 2003 and 2012. Figure 133 shows the bimonthly distribution of boat-based fishing effort over the same time period. Skipjack tuna are the most commonly recreationally caught pelagic fish (Figure 129) followed by yellowfin tuna, mahimahi and wahoo. In terms of weight, however, yellowfin tuna dominates recreational pelagic fish catches (Figure 130).

Although blue marlin numbers in the catch are small compared to other species, the much greater average weight (Figure 131) means that it can comprise a significant fraction of the recreational catch by weight. Average weights for most species tended to be relatively similar between years for mahimahi, skipjack and wahoo, but may vary considerable between years for blue marlin, striped marlin and yellowfin tuna. This is also reflected in the nominal catch rate (lbs/trip) in Figure 132, where yellowfin catch rate was high in 2003, declined in 2004 and 2005, and then increased with peaks in 2009 and 2011. The distribution of fishing recreational fishing effort shows that boat based activity is highest in the summer and fall when the weather is at its most clement in Hawaii (Figure 133).

Appendix 1: 2012 Pelagic Plan Team Members

Pelagics

Mr. Keith Bigelow (CHAIR)	NMFS Pacific Islands Fisheries Science Center
Dr. Christofer Boggs	NMFS Pacific Islands Fisheries Science Center
Mr. Michael Fujimoto	Hawaii Division of Aquatic Resources
Mr. Russell Ito	NMFS Pacific Islands Fisheries Science Center
Dr. Pierre Kleiber	NMFS Pacific Islands Fisheries Science Center
Mr. Brent Tibbats	Guam Division of Aquatic & Wildlife Resources
Mr. Paul Bartram	Akala Products Inc.
Mr. Nonu Tuisamoa	American Samoa Dept. of Marine & Wildlife Resources
Mr. Tom Graham	NMFS Pacific Islands Regional Office

Ex-officio Members of All Plan Teams

Mr. Michael Quach	NMFS Pacific Islands Fisheries Science Center
Mr. Reginald Kokubun	Hawaii Division of Aquatic Resources
Mr. Justin Hospital	NMFS Pacific Islands Fisheries Science Center

Appendix 2: Glossary of Terms and List of Acronyms

Glossary of Terms

TERM	DEFINITION
Alia	Samoan fishing catamaran, about 30 feet long, constructed of aluminum or wood with fiberglass. Used for various fisheries including trolling, longline, and bottomfishing
Bycatch	Fish caught in a fishery but discarded or released, except in a recreational fisheries catch and release program.
Commercial	Commercial fishing, where the catch is intended to be sold, bartered, or traded**.**
Guam	A U.S. territory in the Marianas Archipelago. South of and adjacent to the Commonwealth of Northern Marianas Islands.
Hawaii	U.S. state. See MHI, NWHI. Composed of the islands, atolls and reefs of the Hawaiian Archipelago from Hawai'i to Kure Atoll, except Midway Islands. Capitol - Honolulu.
Ika-shibi	Hawaiian term for night tuna handline fishing method. Fishing for tuna using baited handlines at night with a nightlight and chumming to attract squid and tuna.
Incidental Catch	Fish caught that are retained in whole or part, though not necessarily the targeted species. Examples include monchong, opah and sharks.
Interaction	Catch of protected species, which is required to be released. Examples: Hawaiian monk seals, marine turtles and albatrosses.
Logbook	Journal kept by fishing vessels for each fishing trip; records catch data, including bycatch and incidental catch. Required in the federally regulated longline and crustacean fisheries in the Hawaiian EEZ**.**
Longline	Fishing method utilizing a horizontal mainline stretching from several hundred yards to many miles in length, suspended for the surface by floats, to which droppers with baited hooks are attached.
Longliner	Fishing vessel specifically adapted to use the longline fishing method.
Palu-ahi	Hawaiian term for day tuna handline fishing. Fishing for tuna using baited handlines and chumming with cut bait in a chum bag or wrapped around a stone. Also, drop-stone, make-dog, etc.
Pelagic	The pelagic habitat is the upper layer of the water column from the surface to the thermocline. The pelagic species include all commercially targeted highly migratory species such as tuns, billfish and some incidental-catch species such as sharks, as well as coastal pelagic species such as akule and opelu.
Pole-and-Line	Fishing for tuna using poles and fixed leaders with barbless lures and chumming with live baitfish. Poles can be operated manually or mechanically. Also, fishing vessels called baitboats or aku-boats (Hawaii).
Protected	Refers to species which are protected by federal legislation such as the Endangered Species Act, Marine Mammal Protection Act, and Migratory Bird Treaty Act. Examples: Black-footed and Laysan albatrosses, marine turtles, dolphins.
Purse seine	Fishing for tuna by surrounding schools of fish with a very large net and trapping them by closing the bottom of the net.
Recreational	Recreational fishing for sport or pleasure, where the catch is not sold, bartered or traded.

Sanctuary	Protected area. Commercial/recreational fishing may be restricted.
Secretary	When capitalized and used in reference to fisheries within the U.S. EEZs, it refers to the U. S. Secretary of Commerce.
Small pelagics	Species such as akule (big-eye scad - *Selar* spp.) And opelu (mackerel scad - *Decapterus* spp). These fish occur mainly in shallow inshore waters but may also be found in deeper offshore waters. Not part of the PMUS.
Trolling	Fishing by towing lines with lures or live-bait from a moving vessel.

List of Acronyms

Acronym	Meaning
AP	Advisory Panel. Appointed industry/government/educational representatives functioning in an advisory capacity to the Council.
AS	American Samoa. Includes the islands of Tutuila, Manua, Rose and Swains Atolls.
ASDPW	Department of Public Works, American Samoa. Also, DPW.
ASG	American Samoa Government
CNMI	Commonwealth of the Northern Mariana Islands. Also, Northern Mariana Islands, Northern Marianas, and NMI. Includes the islands of Saipan, Tinian, Rota, and many others in the Marianas Archipelago.
CPUE	Catch-Per-Unit-Effort. A standard fisheries index usually expressed as numbers of fish caught per unit of gear per unit of time, eg., number of fish per hook per line-hour or number of fish per 1,000 hooks. The term catch rate is sometimes used when data are insufficiently detailed to calculate an accurate CPUE.
DAWR	Division of Aquatic & Wildlife Resources, Territory of Guam.
DBEDT	Department of Business, Economic Development & Tourism, State of Hawaii.
DFW	Division of Fish & Wildlife, Northern Mariana Islands.
DLNR	Department of Land & Natural Resources, State of Hawaii. Parent agency for Division of Aquatic Resources (HDAR).
DMWR	Department of Marine & Wildlife Resources, American Samoa. Also, MWR.
DOC	Department of Commerce. In this annual report, it refers to the American Samoa Government.
EEZ	Exclusive Economic Zone, refers to the sovereign waters of a nation, recognized internationally under the United Nations Convention on the Law of the Sea as extending out 200 nautical miles from shore. Within the U.S., the EEZ typically is between three and 200 nautical miles from shore.
ESA	Endangered Species Act. An Act of Congress passed in 1966 that establishes a federal program to protect species of animals whose survival is threatened by habitat destruction, overutilization, disease etc.
FAD	Fish Aggregating Device; a raft or pontoon, usually tethered, and under which, pelagic fish will concentrate.
FDCC	Fishery Data Coordinating Committee, WPRFMC.
FEP	Fisheries Ecosystem Plan

FFA	Forum Fisheries Agency. An agency of the South Pacific Forum, which comprises the independent island states of the South Pacific, Australia and New Zealand. The FFA formed to negotiated access agreements between FFA member countries and distant water fishing nations such as Japan and the USA.
FMP	Fishery Management Plan.
HDAR	Hawaii Division of Aquatic Resources. Also, DAR.
HIMB	Hawaii Institute of Marine Biology, University of Hawaii.
HMRFS	Hawaii Marine Recreational Fishing Survey
HURL	Hawaii Undersea Research Lab.
JIMAR	Joint Institute of Marine and Atmospheric Research, University of Hawaii.
IATTC	Inter-American Tropical Tuna Commission.
Lbs	Pounds
MFCMA	Magnuson Fishery Conservation and Management Act of 1976. Also, Magnuson-Stevens Fishery Conservation and Management Act of 1996. Sustainable Fisheries Act. (Also, MSA)
MHI	Main Hawaiian Islands (comprising the islands of Hawai'i, Mau'i, Lana'i, Moloka'i, Kaho'olawe, O'ahu, Kauai', Ni'ihau and Ka'ula).
MRFSS	Marine Recreational Fishing Statistical Survey
MSY	Maximum Sustainable Yield.
mt	Metric tonnes
MUS	Management Unit Species
NMFS	National Marine Fisheries Service, National Oceanic and Atmospheric Administration, Department of Commerce. Also NOAA Fisheries.
NOAA	National Oceanic and Atmospheric Administration, U.S. Department of Commerce.
NWHI	Northwestern Hawaiian Islands. All islands in the Hawaiian Archipelago, other than the Main Hawaiian Islands (MHI).
OFP	Oceanic Fisheries Program of the South Pacific Commission.
OY	Optimum Yield.
PIFSC	Pacific Islands Fisheries Science Center
PIRO	Pacific Islands Regional Office, National Marine Fisheries Service. Also, NMFS PIRO.
PFRP	Pacific Pelagic Fisheries Research Program, JIMAR, University of Hawaii. Also PPFRP.
PMUS	Pacific Pelagic Management Unit Species. Also, PPMUS. Species managed under the Pelagics FMP.
PPGFA	Pago Pago Game Fishing Association
PT or PPT	Pelagic Plan Team. Advisory body to the Council composed of scientists and fishermen who monitor and manage the fisheries under the jurisdiction of the Pelagics FMP.
SAFE	Stock Assessment and Fishery Evaluation, NMFS.

SPC South Pacific Commission. A technical assistance organization comprising the independent island states of the tropical Pacific Ocean, dependant territories and the metropolitan countries of Australia, New Zealand, USA, France and Britain.

SPR Spawning Potential Ratio. A term for a method to measure the effects of fishing pressure on a stock by expressing the spawning potential of the fished biomass as a percentage of the unfished virgin spawning biomass. Stocks are deemed to be overfished when the SPR<20%.

SSC Scientific & Statistical Committee, an advisory body to the Council comprising experts in fisheries, marine biology, oceanography, etc.

USCG U.S. Coast Guard, 14th District, Department of Transportation.

USFWS U.S. Fish & Wildlife Service, Department of Interior. Also, FWS.

VMS Vessel Monitoring System. A satellite based system for locating and tracking fishing vessels. Fishing vessels carry a transponder which can be located by overhead satellites. Two-way communication is also possible via most VMS systems.

WPacFIN Western Pacific Fishery Information Network, NMFS.

WPRFMC Also, the Council. Western Pacific Regional Fishery Management Council. One of eight nationwide fishery management bodies created by the Magnuson Fisheries Conservation and Management Act pf 1976 to develop and manage domestic fisheries in the U.S. EEZ. Composed of American Samoa, Guam, Hawaii, and Commonwealth of Northern Mariana Islands.
